41423. Help TS-830S S-meter and ALC readings high on meter - 9 Volt regulator issues

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-21 22:32:29 UTC
From: dchristensen70
Topic: 41423 Message: 41423

I posted this earlier but forgot to include the radio type.

I have a TS-830S that has developed a problem with the ALC meter (and I think the S meter) reading. With the radio in tune mode and the carrier control fully counter clockwise the ALC meter reads in the middle of the range. Advancing it even slightly (beyond the 8 o'clock position) pegs the meter making it hard to peak the drive. When tuned and transmitting in SSB the ALC meter pegs with almost no power being generated.

I noticed the other night that S-meter readings appear to be quite high when compared with another radio - The TS-830 is tracking with other radios but reading several S-units higher.

This might have happened when I had a bad section of coax that was presenting a high SWR to the radio on transmit.

The HV meter setting seems normal, the IP Bias on SSB transmit is reading normal (60ma), the RF meter setting seems to track an external power meter. Just the S-meter and ALC is off.

More information: The voltage reading at TP6 on the audio board was reading 10.46 volts when I first checked it. With VR4 all the way counter clockwise the lowest voltage I can get is 9.958 Volts and it slowly creeps up with power over time. When I shut the rig off it was reading 9.968 Volts and still slowly climbing.

The 3.6 Volt reading on pin 5 of the AF connector was a bit high (3.9 V) but I have adjusted the setting to 3.62 volts and it fluctuates a bit up and down but stays within 0.05 volts of this setting

The S-meter with nothing attached to the antenna reads S3.5. Terminated to a 50 Ohm dummy lod it reads S-8-9 with the AGC in Slow position. When the AGC switch is off it reads S3.5.

I think I have a 9 volt regulator circuit is goofy and perhaps the over sensitive ALC settings on tuneup/transmission are also related.

Thanks and 73

Dave - KD7UM

Mike/ w9mvm,

  If I may answer in the other Mikes place. When the final amplifier tubes are changed, always neutralize! On another note: checking the 6146 series or, other RF output tubes for that matter, on a "tube checker" will not assure that the tube(s) will function correctly/adequately in the "real" RF environment. The best way...in my humble opinion..is to check them on the "tester" and put 'em...neutralize..and see how they function.

Hi Mike, I know what you are saying is correct. I enjoy you email directions. One question. Is it necessary to go through the neutralization procedures if installing used 6146's if the the used tubes check-good.?? or only installing new 6146's?? Thanks.

BEST 73s and GODS BLESSINGS, MIKE W9MVM

The Taylor tubes are made in China, like most of the others on Ebay etc. I tried a pair for my 830S, and was very disappointed. They did not make much power.

I called RF parts, and I will say that they took them back without any grief. The fellow I talked to recommended trying a pair of Phillips 6146W tubes of which they had a limited supply. They cost about $10.00 more than the Taylor tubes, and are fantastic. I can get full rated power out while drawing a minimum amount of current.

Well worth the extra money! If they have any more, I would buy a pair.

Also having a matched pair is not that important because you will be running them in parallel, not push-pull.

hi Rick,

New old stock JAN Military circa 1987 RCA Made in USA
tubes for final and the driver.

http://www.surplussales.com/Tubes-Sock-Acc/TubeSpecials.html

6146W $22 each 12BY7A $10

you don't need a matched pair in the Kenwoods
and the driver don't need to be changed when you
change the finals unless it is going bad or has failed.

Another vote for EBAY three tube sets, the 12BY7 driver and two 6146Bs. I bought a set for my TS-520 and they were NOS as advertised and excellent quality
GE tubes in the boxes.

Hi Joe & Mike, Just wanted you both too know-my Kenwood TS-520SE is up and running GREAT!! Thank you both for all of your info. and help.This group is very fine, for sure. I have a new ALINCO DX-SR8T which is a great radio (3 weeks "old" now) But, my TS-520 is my primary HF rig and now adding this TS-520SE along with it.

BEST 73s and GODS BLESSINGS, MIKE W9MVM

Topic: 41372 Message: 41430

Mike,

Yes, I recommend you perform the neutralization procedures found in the service manual, regardless whether the tubes are NEW or USED.Neutralizationrequirement is not about whether the tube(s) are NEW or USED.You might take some time and read Tom Ranch, W8JI, website on "Neutralization" (see the following link). While this link is primary focused on ground grid amplifiers, it does provide significant insight in amplifier neutralization.

http://w8ji.com/neutralizing__amplifier.htm

A ham license does not automatically convey electronic knowledgeand experience. Electronic knowledge, troubleshooting and repair experience is something you learn by "studying"and putting what you have learned into practice.

I don't know what your electronic knowledge, troubleshooting, and repair skill level is. Attempting to service a sophisticated transceiver such as a Kenwood hybridfor example, without any electronic knowledge, troubleshooting and repair skills, is the same as jumping into the deepest end of the swimming pool, not knowing how to swim! If you skills in those areas are slim to none then may I recommend you pick up an older edition of the ARRL handbook, anyedition between 50s and 70s is a good choice, (many can be found onebay at cheap prices) and start learning basic electronics. Basic Electronics does NOT become obsolete because of age. A resistor passing current in 1950 will do the same thing in 2013! Don't jump ahead to the advance subjects, learn the basics FIRST. Another book I highly recommend is "The Basic Radio Course" by John T. Frye. This book is out of print but can quite often be found on the web. I found my copy at a used book store, in hard copy, for $2.00. Your local library may have it.

Hi Joe & Mike, Just wanted you both too know-my Kenwood TS-520SE is up and running GREAT!! Thank you both for all of your info. and help.This group is very fine, for sure. I have a new ALINCO DX-SR8T which is a great radio (3 weeks "old" now) But, my TS-520 is my primary HF rig and now adding this TS-520SE along with it.

BEST 73s and GODS BLESSINGS, MIKE W9MVM

41432. TRIO KENWOOD TS-515 technical manual (service manual)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-22 09:25:47 UTC
From: Behiels JeanPierre
Topic: 41432 Message: 41432

Hi Kenwwod members;

Is there anybody who could supply me a copy (a pdf file is already OK for me) of the service manual of the above transceiver.
The user manual is free of charge to find on the net but the service manual is no available ?
I suppose there is still a service manual published in the past ?
I found the service manual for the TS-510 but TS-515 seems to be rare.
I hope someone could help me with my request.

Best regards Jean ON4AEF.

Glad to see the 520SE is working. I had a 520SE with the DG-5 many years ago. Have fun.

Topic: 41392 Message: 41434

Jack:
Then the problem is elsewhere.
If a mic is the wrong impedance it just does not work, wrong impedance is not associated with hum.
500 ohm is actually a medium value for a mic impedance, 50K ohm is high. 500 ohm mics work well with the hybrids however, I bought a Karioke mic at Goodwill for $2 and it works fine (500ohms). Low impedance mics need a preamp that really just changes the impedance.
I would try another mic first, then look the unit.
Check the connections on the mick jack on the unit on the back of the front panel, maybe one is loose or broken.
If its just hummmmmm, could it be 60Hz from the power supply?
You could check the mic pins with a scope to see if there is some 60 cps on the pins (or anywhere else). Otherwise it could be anywhere in the transmit chain, but could start in the power unit low voltage supply. I think this is the 14V (16V?) supply. Maybe the electrolytic caps are bad in the LOW volt supply. That would be a cheap and easy fix, these are smaller, easily available caps. I think there are pins on one power board that are marked 14AC and 14DC. If there is 60HZ on the DC pins you need to fix it.
I am not familiar with the mic, is it plastic or metal?
If it's metal Make sure the metal case is well grounded.
But metal cases just act like antennas for RF but the RF does not sound like 60Hz hum.

Pete:
Cartridges and mics are much different in their pick up pattern. D 104 mics will pick up anything in the room, for example. If your Shure cartridge is from a Base mic, the kind with a metal stand, it will do the same. Cardiod patterns are mostly dictated by the enclosure.
Mostly hand mics and hence their cartridges, are designed for mobile use where you have lots of noise and need to hold the mic up to your mouth.
If you are interested in experimenting and like the Motorola enclosure, you could go to a local CB shop and buy old CB mics for a buck each and try their cartridges (maybe they will give them away). Some are surprisingly good.
For handling noise you could try sound deadening material, perhaps parts of a paper egg carton. Sound deadener material used to have lead in it, I don't know what is currently available. Maybe left over refrigerator magnets would work. You can cut them to fit.
You could evaluate the sound deadening of a material by putting it in front of a small speaker and seeing if it deadens the sound.

Rick
I think you are referring to the little choke. I think it is about 6.8 micro henries. The exact value is not critical. You could use anything close, perhaps even several times the value. I once made one up by winding 6 six turns of enameled wire through a very small toroid. It works.
You just measured the DC resistance of the wire, not the ferro magnetic effect of the core (on RF).
If the big upright choke is the issue, it must be rewound by hand, none available. This is a pain. This is again not critical and using the same size magnet wire for the same distance(rather than counting the turns) on the ceramic tube will work fine. Mark the ceramic form before removing the old wire.
I think Ken http://www.n6wk.com still sells a rebuild kit that includes the little choke and new high voltage caps and I did use one of his kits. They are good and the price is OK. You can spend lots more time finding the parts and pay a little less. If you are working on the final, this is a good thing to do while you are in there.
I think he discusses the issue on his website. It is worthwhile reading.
If the little choke blew you may have cap trouble that caused it.
Also the little choke can arc to the metal base of the final tubes and is mounted very close to them. The orignal S2001 tubes had plastic bases.

Rick:

Before you crank her up I strongly recommend you go to ebay and buy a used but tested good set of 6146's or 6146A's. They will work in the set but might not put out the same power. And the same for a couple of 12BY7A's.

There is no reason to fry a good set of 6146B's while you learn to operate the radio and do troubleshooting. In my TS-820S, which was received with many problems, I pulled the 6146B's, not trusting them anyway, and proceeded to install a used set of S2001A's. I wore them down with many Tune and transmit cycles and eventually killed them when a connector came loose while I was fixing another problem. Once I got it all working properly, I put the 6146B's that came with it and all was well. In the process I went through a couple of cheap used 12BY7A's as well.

Another option is to pick up a cheap set of 6883B's (e.g. $20 for the pair). They are 6146B's with 12V filaments. It is simple to rewire the filaments for 12V. I may try that with the TS-520 I am repairing now.

Good Luck!

Robert

Hi Wally,

Thanks for the tips. I ordered a final rebuild kit the other day. It should be here next week. I don't feel the little choke (L1) will cure the problems I am having, but I was in there and it was charred black from over heating too many times, so, I decided to replace it along with the other items in the kit. I'm sure the finals are weak or they tested weak on my old Hickock. I can still get full power after an hour or so warm up on all bands but 160 and it is dead. Probably a VFO issue.

Thanks again,

Rick/K5IAR

Rick
I think you are referring to the little choke. I think it is about 6.8 micro henries. The exact value is not critical. You could use anything close, perhaps even several times the value. I once made one up by winding 6 six turns of enameled wire through a very small toroid. It works.
You just measured the DC resistance of the wire, not the ferro magnetic effect of the core (on RF).
If the big upright choke is the issue, it must be rewound by hand, none available. This is a pain. This is again not critical and using the same size magnet wire for the same distance(rather than counting the turns) on the ceramic tube will work fine. Mark the ceramic form before removing the old wire.
I think Ken http://www.n6wk.com still sells a rebuild kit that includes the little choke and new high voltage caps and I did use one of his kits. They are good and the price is OK. You can spend lots more time finding the parts and pay a little less. If you are working on the final, this is a good thing to do while you are in there.
I think he discusses the issue on his website. It is worthwhile reading.
If the little choke blew you may have cap trouble that caused it.
Also the little choke can arc to the metal base of the final tubes and is mounted very close to them. The orignal S2001 tubes had plastic bases.

Thanks for the advice, Robert. I have many old 6146's, S2001A's and 12BY7A's that I've been using during repair. I am very familiar with the 820 as it is almost identical to my TS-520 I have been using for many, many years. This one has been sitting for a number of years in a controlled environment. Most of the problems have been solved by exercising the controls, switches and cleaning the plugs and sockets on the boards. I had to replace Q25 in the processor to get it going and a couple of electrolytic capacitors, but other than that it's been mostly cleaning.

Thanks again!

Rick/K5IAR

Rick:

Before you crank her up I strongly recommend you go to ebay and buy a used but tested good set of 6146's or 6146A's. They will work in the set but might not put out the same power. And the same for a couple of 12BY7A's.

There is no reason to fry a good set of 6146B's while you learn to operate the radio and do troubleshooting. In my TS-820S, which was received with many problems, I pulled the 6146B's, not trusting them anyway, and proceeded to install a used set of S2001A's. I wore them down with many Tune and transmit cycles and eventually killed them when a connector came loose while I was fixing another problem. Once I got it all working properly, I put the 6146B's that came with it and all was well. In the process I went through a couple of cheap used 12BY7A's as well.

Another option is to pick up a cheap set of 6883B's (e.g. $20 for the pair). They are 6146B's with 12V filaments. It is simple to rewire the filaments for 12V. I may try that with the TS-520 I am repairing now.

Good Luck!

Robert

If the 820 works on all bands but is dead on 160, the problem is not
the VFO. More than likely the problem is caused by a failure in the
160 meter VCO, Q2 on the VCO board, in the PLL Unit.

The VFO is not controlled by nor is it's output and frequency
switched and changed by the band switch. The VFO output is
applied to the PLL Unit at PLL-1 pin 2 (VFO signal) and
pin 1 (GND).

I would check the 160 meter VCO for the source of your problem
on 160.

No, it occurs mainly while I am tuning the radio - moreso after changing bands and when I adjust the drive control while in send.

After the power output drops and I flick out of send, receive is also nearly dead - as though I have turned down rf gain or turned on the attenuator. A on/off power cycle brings back receive but same fault occurs when I try to do the tune process

Jean,

I had to make a cable for my TS-511S (US version of TS-515). The connectors are an old Cinch-Jones connector that is now produced by Molex (Beau Series). Mouser has both parts in stock.

Plug: Molex #38331-5612, Mouser# 538-38331-5612
Socket: Molex #38331-8012, Mouser# 538-38331-8012

Regards,

Thanks, Mike. I guess I assumed it might be a VFO problem because when I tune other bands I get a little intermittent operation at times as if something is a little dirty or not making good contact. I should have made myself more clear. The 160 meter receive is fine it's just no transmitter drive.

I will definitely follow your advice and check the 160 meter VCO, Q2 in particular.

Thanks a million!

Hi Wally and thanks for the reply. You hit it right on the head. The Shure cartridge was from an old deck mic. I'll stuff some pieces of paper egg carton around the element and try that. I hadn't considered CB mics as a source of elements and have a ham friend that has several. Maybe he will part with a couple for test purposes.
Once again thanks for great advice.

Pete:
Cartridges and mics are much different in their pick up pattern. D 104 mics will pick up anything in the room, for example. If your Shure cartridge is from a Base mic, the kind with a metal stand, it will do the same. Cardiod patterns are mostly dictated by the enclosure.
Mostly hand mics and hence their cartridges, are designed for mobile use where you have lots of noise and need to hold the mic up to your mouth.
If you are interested in experimenting and like the Motorola enclosure, you could go to a local CB shop and buy old CB mics for a buck each and try their cartridges (maybe they will give them away). Some are surprisingly good.
For handling noise you could try sound deadening material, perhaps parts of a paper egg carton. Sound deadener material used to have lead in it, I don't know what is currently available. Maybe left over refrigerator magnets would work. You can cut them to fit.
You could evaluate the sound deadening of a material by putting it in front of a small speaker and seeing if it deadens the sound.

I think you were right the first go around, Mike. I think Q2 is defective. I do get a signal from my generator up and down the 160 meter band, however, I just checked the voltages on Q2 and they are all off a lot. The base has zero voltage, the collector voltage is way down and the emitter voltage about twice as much as it should be. So, Q2 cannot be performing correctly. I'm not sure the device is to blame or something in the associated circuitry. I had a NTE cross match for Q2 and installed it. The voltages were much closer but the receiver was dead on 160 and within a few minutes the voltages were zero or almost zero on all legs of the NTE transistor. So much for subs. I've located a 2SC460, but it is not the (B) version so I'm not sure it will stand the test either. I'll get it tomorrow and find out. I put the original device back into the circuit and I'm back where I started.

Rick

If receive on 160 is okay but transmit is not working then
not the 160 meter VCO. The VCO, selected by the band switch,
functions in both transmit and receive. Verify the presence of the
TIF signal at the RF Unit's RF1 pins 9 and 10 on 160.

Most of the Motorola mobile radio mics have a low Z and an amplifier integrated into the mic, So they use unshielded cords.
 A higher Z input on most ham gear needs shielding. May be the cause of your hum !

You DON'T need "Matched" tubes in a parallel tube amp ! They just both have to work ! they both should be the same Type number as in 6146A, 6146B or S2001.
I see this urban legend about needing specially "matched" tubes in the hybrid radios every month on this group !
.

My service manual has detailed alignment instructions. Make sure you align each band in order and have the VFO set to the recommended freqs.
You have to do the entire alignment and don't try to just do one band, results are not what you expect if you try one band..

Subject: [TS-520_820_530_830] Drive at the high end of 75 meters.

Hi to all.
I have a TS-520 that works very well except at the high end of 75 meters. The normal drive level is indicated on the meter in normal tune-up up to about 3.75 MHz. From there on up the needle will drop off gradually to zero at about 3.82 MHz. All the other bands show normal drive levels at both ends. Power output is normal when the drive is tuned up.
I just obtained this rig from QTH.com and it is excellent in every respect except this. I've changed driver tubes and the trouble is there with both of them. It appears that the coil pack associated with 75 meters needs adjusted. I have the operating and service manuals but they have no guidance about this.
Would anyone have an idea how to resolve this problem?
Thanks & 73,
Pete WW3O

To DC it is just a thin piece of wire. close to Zero, maybe a few tenths of an ohm.

Hi Guys;

Anyway thanks all for your help.
Yes I now this website very well.
But the technical manual of the TRIO KENWOOD TS515 is not available on this website.
And it exist for sure,it is the manual with all the PCB designs and detailed schematics of each unit behind the TS515.
Nobody nows about ??
I have the impression it is for sure a rare object to obtain ?

Regards Jean ON4AEF.

Topic: 41460 Message: 41460

My VFO230 is stable for about half an hour after TS830 switch on - then becomes a little flaky in its frequency readout. Not much mind but slowly turning the dial can sometimes not even shift the frequency. Fast turning of the dial seems to work. I have re-tightened all PCB mounting screws and disconnected and reseated all PCB plug in connections.
Anyone with any ideas?
Thanks
William

Hi Kenwood uergroup members;

I am chearching for the mechanical/reduction setup of the VFO of a old KENWOOD TS515
The shaft has and the mecanical transfer/reductor has been wore out due the intensif use before !!
Nobody who has perhaps a VFO unit in spare for sale or not use anymre or in surplus.
I hope somebody could give my some good advise or adresses where I possibile could buy some spare parts.
Thanks to all anyway..

Regards Jean ON4AEF.

Topic: 41463 Message: 41463

Hi members;

The original sweep finals of those both TRIO KENWOOD transceivers (6LQ6 ans S2001) are very difficult to find and expensif!!
Is it not possible by doing some minimal modifications to use some more available final tubes like 6146.
Of course tube sockets has to been changed has major modification,but I saw that both types have same filament voltages.
Ohter voltages like grid and anode supplys are quit same,isn't ?
I am thinking around this subject to change the final types if possible ?
Some more advice around this subject will be mutch appreciated ..

Regards Jean ON4AEF.

G'day William,

Gordon is correct, but saying that I have two VFO 230s, if I leave them turned off (disconnected from power) for more than a month I have the same issue, I usually leave it connected to power for 24 hours without having it connected to radio when I turn it back on it doesn't miss a beat, know a few people who have had the same issue and as they leave it connected to mains power they never have the problem again. So would be interested in know if you leave it connected to power?

From: John Donnelly
Topic: 41392 Message: 41469

My problem was solved by picking up an MC-50. The original hand held that was causing the transmit hum
is a Kenwood that originally shipped with a TS-520. The only markings on the mic itself other than "Kenwood"
are on the back:

  Dynamic mic
     500 ohm
       Japan"

BTW, the mic works fine on the TS-520 that it came with - no hum problem at all on transmit. Go figure. The only thing I can think
of is that the impedence difference between the MC-50 and the had held is making the older mic more susceptible to picking up hum.

Thanks for all the suggestions from the group.

41470. KENWOOD HYBRID USER NET (March 24th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-24 18:48:39 UTC
From: mvgilger
Topic: 41470 Message: 41470

The Saturday's net on 40 meter we had 23 stations checking with good band conditions. There were 2 new stations checking in. Out of those, there was:

6 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 13 stations checking in under very poor band conditions. We had 1 new check-in, N5CBB.

Out of those, there was:

4 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Sorry ... it doesn't do anything wrong , the gentleman told me it had a transmit problem & I figured I'd repair it ... I hadn't hooked a mic to it yet , and before I could ... he sent me an e-mail stating that the mic he had been using was actually bad , and the radio was probably fine ... when I hooked the mic up to it , sure enough , it was fine . :)

--- In TS-520_820_530_830@yahoogroups.com, "kc2mru" <KC2MRU@...> wrote:
>
> sorry I didn't reply right away ... I had got this rig from another operator , and when we were talking about making the deal he said that it received fine , but it's transmit wasn't very good at all . So I made this post while I was waiting for the radio to get here. The radio just arrived , it's extremely cold from riding in the delivery truck all day ... but I took a look inside to see what I could find out , and this is what I found (so far) : I found a batch of wires that appear to be coming from the digital frequency counter that was unplugged ... and then after looking around a bit more , I found that the 12BY7A driver tube wasn't plugged into it's socket .

Hi guys.
I would like to ask if there is around pin configuration to join R820 to Ts820.
At the moment i have pin 4 nothing else. Meaby can be' a good job to post like a file for all are interested to use the R with TS in separate vfo or trcv operation.

41475. All fixed - Re: TS-830S - 1W power out?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-24 21:43:28 UTC
From: rolandver109
Topic: 40802 Message: 41475

Many thanks Joe and Terry

My TS-830S bought as for part i now up and running. Output power 100W and 0.76V RMS over 8R with 0dbuV RF-in.
Story:
To begin with I replaced al electrolytic capacitors, washed al circuit boards in Isopropanol and then cleaned the inside with Speedball and Isopropanol. After that the TS-830S was completely dead. After several hours of fault tracing I went back to the first rule in the "Ten demands of debugging" that says "Check hardware". Found a broken wire behind the front to the -7V bias for the IF-boards.
Re-solder the wire and the TS-830S was back too what is was before cleaning etc. - weak audio and 5W output power.
Then I began to study the level diagram from the service manual. First I tried to put in 0dbuV and measure the levels, did not work. Raised input level to 20dBuV and I was able to measure voltage on the RF-board ☐ but confusing, the 1Meg probe loaded and levels was inflected.
Then I searched this forum and found the explanation for the TS-830_RX_Level_Diagram.pdf under files. That explained everything, thank you Terry K9TW.
I traced the problem to a very weak BFO signal to the AF-detector. Instead off 300mV it was about 30mV. Also the level from the VBT oscillator 3.750MHz was low.
I made Item t 1 -7 in the alignment guide from the service manual, including adjustment of the entire IF oscillator frequencies and levels.
Audio level and receiver sensitivity are now in specification and so is also output power.
Next step in my long time planing will be to do the rest of the alignment. Is there any way around using the sweep generator? My radio test equipment is a HP8657B signal generator, a HP8508A Vector Voltmeter and an HP8591EM spectrum analyzer. Also recently a 100W dummy load, a Zetagi 700 power meter and 100W 30dB attentuator. No plans to buy anything expensive as I will retire in a year or two.

Regards / Roland

Story:
To begin with I made an comlete replace of all electrolytis C

>
> Roland,
> Assuming that the driver tube and the finals are OK, I would suggest that you check Rf voltages according to the Transmit Rf level diagram on page 44 of the service manual. This may give you an indication as to why you are not getting drive (since your ALC reading in Tune mode seems to be zero). Most of these measurements are done with the SG switch OFF so as not to stress the final tubes.
> You will need to use an Rf probe and a digital multimeter or VTVM. I made my own Rf probe from two 1N60 diodes in series, a 0.01 uf ceramic cap (500 volts or more), and 4.7 megohm resistor, according to circuit diagrams in the ARRL handbook or on the internet.
>
> On the Rf board you would first measure the Rf voltage at TP-4 which should be around 2.0 Rf volts. You should also measure the VCO voltage at TP-3 which should be around 1.0 Rf volts. I suggest doing these measurements at 14.175 MHz. If both of these voltage readings are OK, then you know that the mixer should be providing sufficient Rf drive to the driver

tube. If these voltages are very much lower than there may be a problem on the IF board or even on the PLL board.
>
> If you are getting the correct voltages at TP-4 and TP-3, then the next item to check is the Rf drive on pin 7 (the plate) of the driver tube. This requires a device called a Pomona socket, which can be found on eBay. With the Pomona socket in place you can also check that you have the correct DC voltages to pins 7, 8, and 2 to make sure they are within spec. CAUTION-the EXPOSED PINS ON THE POMONA SOCKET WILL HAVE HIGH VOLTAGES (Pin 7 about 330 volts). Rf drive to pin 7 should be about 75 Rf volts, but I have found it to be somewhat lower and I still can get 100 watts output from the rig.
>
> For each measurment, be sure to record the positions of the Drive and Carrier controls. You will need these for future reference.
>
> I hope this will be a good start in your analysis of the low output problem you are having. Terry Wagner first gave me the advice to do the above, and I was able to correct problems with my TS-830S.

41476. TS-820S for sale or trade

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-24 22:37:53 UTC
From: Bruce Gentry
Topic: 41392 Message: 41476

It is a TS-820s with the MC-50 desk microphone and Kenwood HS-5 headphones. The lever for the AGC speed switch is missing, but the switch is intact and functions fine if you use something to click it. It had a problem in the IF board when I got it, and I repaired it. It's clean and in good to very good cosmetic shape. The digital display is bright and works fine. The output tubes are original but put out well, the DC power unit is not installed. I'm in Syracuse, New York. The goal of this sale/trade is to get a Yaesu VX-8DR handheld. I must emphasize the "DR" model suffix. The others are not of interest. I don't mind if it's dirty, slightly scratched, or fingerworn as long as it's complete, nothing is broken, and it works well. If you have or can find one, I am looking for an even swap. Otherwise, $400.00 plus shipping from zipcode 13211. Several pictures are available on request. Thanks,

Bruce KA2IVY

I had a SWAN 1200 W that used the 6LQ6 tubes.
Found that I could use 6MJ6 and 6ME6 tubes as direct (99%) substitutes.
In fact I ran 2 6LQ6, and one each or the 6ME6 and 6MJ6 tubes.
Just made sure that they were close to equal in strength.
Used a 5 second plate current reading at 0 volt bias and of course individually.

Hi members;

The original sweep finals of those both TRIO KENWOOD transceivers (6LQ6 ans S2001) are very difficult to find and expensif!!

Is it not possible by doing some minimal modifications to use some more available final tubes like 6146.

Of course tube sockets has to been changed has major modification,but I saw that both types have same filament voltages.

Ohter voltages like grid and anode supplys are quit same,isn't it ?

I am thinking around this subject to change the final types if possible ?

Some more advice around this subject will be mutch appreciated ..

Regards Jean ON4AEF.

I had a similar "500 ohm Kenwood" mic that came with a new TS700a that had low mod and sounded very bassy when I used it with a TS520. The TS700 was designed for low Z mics and that mic worked fine with it..

From: John Donnelly <jack@...>
To: "TS-520_820_530_830@yahoogroups.com" <TS-520_820_530_830@yahoogroups.com>
Sent: Sunday, March 24, 2013 2:00 PM
Subject: Re: [TS-520_820_530_830] Re: Transmit audio hum with hand held mic

My problem was solved by picking up an MC-50. The original hand held that was causing the transmit hum
is a Kenwood that originally shipped with a TS-520. The only markings on the mic itself other than "Kenwood"
are on the back:

  Dynamic mic
     500 ohm
       Japan"

BTW, the mic works fine on the TS-520 that it came with - no hum problem at all on transmit. Go figure. The only thing I can think
of is that the impedence difference between the MC-50 and the had held is making the older mic more susceptible to picking up hum.

Thanks for all the suggestions from the group.

41479. TS-820 Drive

Date: 2013-03-25 16:25:36 UTC
From: Rick
Topic: 41479 Message: 41479

I'm curious, how many watts drive is normal for each band of the 820? I feel like my drive level is low even though it loads up to the appropriate output wattage generally. This is with exception of the160 meter band which has zero drive even with the carrier level a maximum. The 160 meter receiver works fine, just no drive to the finals for transmitting. In fact, no drive to the driver!

If anyone recalls the amount of drive that is normally present for each band I would appreciate it very much if you'd let me know. I'd like to know if the other bands are behaving normally before going forward with troubleshooting the 160 meter band. I've been building and repairing tube type radios for many, many years, but this is my first foray into the world of hybrids.

Thank,

Rick/K5IAR

HI
My digital counter on my TS 820s seems to be stuck on 9000. From what I have read it looks as if I need to clean some pins. Does anyone have any pictures that might help me? Many thanks in advance
Fred (GM4ALZ)

By "how many watts drive" do you mean the carrier level or the mike gain level required to get signifcant output? You typically have to vary those depending on the band. On my TS-820S and TS-520 10 meters takes a lot more gain than the other bands.

To my knowledge we do not have a way to measure watts of drive to teh finals directly. I suppose you could infer something about how much is there based on the meter readings while in Tune mode.

What kind of ALC indication do you get on 160 meters? My antenna does not work well on 160 meters so I have not bothered to try my 820S there except for limited testing into a dummy load.

Thanks!

Robert

With the drive peaked in ALC metering,,
 the plate dipped in Ip metering
and the load adjusted for the proper Ip current and a plate tuning dip maintained,
 you should get no less than 100 W, except on 10M, a little less is normal there.

I understand. I am working on a 820 and it has drive problems on the lower bands, especially 160 meters. I am wondering if anyone ever noticed how much output their 820 has when set to ALC and TUNE when the 820 meter is peaked? I want to know how many watts of drive (switches at ALC and TUNE) are indicated on a wattmeter when the 820 meter is peaked?

Thanks,

Rick/K5IAR

Good Evening Group:

I wanted to give my fellow members an opportunity to have a "Heads-up" prior to this equipment going onto eBay and / or other outlets for liquidation. If there is an interest in any or all of the units, please contact me, off the list to discuss further.

The items are as follows:

Kenwood AT-230 antenna tuner

Kenwood MC-50 dynamic cardiod desk microphone

Kenwood SM-220 Station Monitor

Kenwood SP-230 external speaker

Kenwood TS-820S Amateur HF Transceiver

Kenwood VFO-820 external analog display VFO

The units have been keep under dust cover, in a smoke free environment. The above are from my primary operating station, and were in use as recently as this past weekend.

tnx es 73 / 76

In the TUNE position with the PLATE control adjusted for an IP dip into 50 ohms and the CARRIER control adjusted for mid range ALC reading and the DRIVE control peaked, I get about 15 watts on most bands. I get around 10 watts on 10 mtrs.

All Hybrids are different. I monitor output during entire tune up. I have repaired a few mostly 530 and 830 but they all act a little different. On 160 thru 20 meters I have rigs that will peak ALC at 10 to 15 watts and others 20 to 25 although the 25 is rare. Depends on the tune circuit and condition of the drive. I believe Kenwood designed the tun circuitry to use about 20% to protect the finals from beginners and heavy handers. If you want to see the difference remove the key phono jack and with the mode switch in tun flip the send switch and check your output. Then set the mode switch to cw and flip the send switch. Big difference. Before you sit there and stare at the output meter flip that send switch back to rec. I have my original 520 and rebuilt it last summer. With new driver and finals I can peak 25 watts out on a Bird 43. That rig has been well taken care of. I used the old finals in another 530 and still get 100 watts on the lower bands.

Thanks, Don. I have my original 520 also and it is still my favorite rig! The only thing I have ever had to do to it was replace the filter capacitors in the high voltage supply. I had one pop on me several years ago and I replaced both of them with originals I ordered from Kenwood. That should tell you how long ago it was, they still had parts for it. HI. I hope to have this TS-820 on the air soon. It's not in bad shape but does have an issue or two I'd like to solve before putting it in the operating position. I discovered just today the 500 ohm potentiometer (V4) on the AV board that controls the Monitor Level is intermittent. I think I have a replacement. If not, I'm sure someone does. When Kenwood built these transceivers they intended them to be a round a long time!

Thanks again for the info.

Maybe only 5-10 watts max.
Mark

I just noticed you are using the TUNE position. I gave you incorrect readings,
I actually hardly ever tuned this way, I always used the CW mode to tune up my 520.
I believe you would get about 1/4 or less normal output
 with the lower screen voltge thru the TUNE position of the mode switch/.

41495. TS-820 - Dip or Peak?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-26 13:10:58 UTC
From: Rick
Topic: 41495 Message: 41495

The loading instructions for the TS-820 state after you dip the Plate current (Ip) while in the Tune and Ip positions you should move the switch to the RF position and peak the meter using the Tune and Load controls. My question or possible problem is, when I do this the peak is not resonant. When I switch back to check the dip or resonance of the Ip I find it is no longer correct. Through the many years of loading transmitters and amplifiers I have always made sure the tank is resonant by dipping the plate last. Am I missing something here or do I have a problem I need to address in my 820?

Thanks,

Rick/K5IAR

As long as you are neutralized properly on 10 meters, per the instructions, you are ok. You will typically always have a little difference between the RF peak and the plate dip. Not much, but some.

An authorized Kenwood tech that still does a lot of work on the hybrid series told me that the best way to tune any of the
boat anchors is to go to the TUNE mode, peak the ALC with the drive control and go straight to the RF position and tune
for peak output. The difference between the peak and dip is minimal and you're not feeding plate current to the antenna,
you're looking for RF power.

Even easier if you have an external watt meter in line. Just peak on it's reading and you won't wear out your switch on the 820.

All that I run between my R-820 and TS-820 is pin #4 on the R-820 to pin 5 on the TS-820 Remote VFO plug. This will mute the R-820 when TS-820 is in transmit mode. Running it this way gives me flexibility to use both VFO's and run the R820 on a separate band as the TS-820 is using, or use both on the same band or same freq. if needed.

Rick,

It's possible, as a previous response stated, the 820's final amplifier neutralization should, at a minimum, be checked and, if necessary, perform the neutralization procedures.

Tom Ranch, W8JI, has an excellent article on his website that discusses neutralizing an amplifiers (see the link below).

http://w8ji.com/neutralizing__amplifier.htm

Although the article covers grounded grid amplifiers, if you scroll down the page you will see the section that covers "Grid Driven" amplifiers which is what the hybrid final amplifiers are. I highly recommend Tom's article as a must read for all members/hams.

I have found that when operating MY TS-820S through an antenna tuner with built in wattmeter and SWR meter it is possible to get two different transceiver control and antenna tuner settings that give "acceptable" RF power out and SWR. However, one will be significantly better than the other. The control settings differ to a degree but the largest single difference seems to be the setting of the LOAD control. For the poorer setting, the LOAD control is set a lot lower; the rest of the settings differ by not so much.

I agree, John. All of my measurements and troubleshooting are wit a dummy load, so, it looks like I have a little problem. I'll try neutralizing it after I install the new L! choke that is charred. I will likely install a couple of the caps in that section too while I'm in there.

Thanks,

Rick

I do have a Bird 43 inline with my dummy load or antenna whichever way it is switched. However, the problem is when the RF is peaked to the wattmeter the Plate Ip is not dipped fully and is therefore not at resonance. I must have a little issue there.

Thanks,

Rick/K5IAR

Even easier if you have an external watt meter in line. Just peak on it's reading and you won't wear out your switch on the 820.

Sure, you can tune it up in CW mode. I usually do a quick check in CW mode after tuning up in TUNE mode, prior to going to SSB.

But if you are as slow to tune and as ham-fisted as I am, you'll burn out your finals faster by not going to TUNE mode first.

Thanks, John. That sounds like good advice. However, the difference between the dip and the peak in my case is considerable. Therefore, I must have an issue that needs solving before moving on.

Thanks,

Rick/K5IAR

An authorized Kenwood tech that still does a lot of work on the hybrid series told me that the best way to tune any of the
boat anchors is to go to the TUNE mode, peak the ALC with the drive control and go straight to the RF position and tune
for peak output. The difference between the peak and dip is minimal and you're not feeding plate current to the antenna,
you're looking for RF power.

As long as you are neutralized properly on 10 meters, per the instructions, you are ok. You will typically always have a little difference between the RF peak and the plate dip. Not much, but some.

Regards,
Mark

Thanks, Mike. Great advice. I will follow the link and read up on the procedure. I've done it a zillion times on my old homebrew exciters and amplifiers, but I am always anxious to hear another view of it.

Thanks and 73,

Rick/K5IAR

Subject: Re: [TS-520_820_530_830] TS-820 - Dip or Peak?

Rick,

It's possible, as a previous response stated, the 820's final amplifier neutralization should, at a minimum, be checked and, if necessary, perform the neutralization procedures.

Tom Ranch, W8JI, has an excellent article on his website that discusses neutralizing an amplifiers (see the link below).

http://w8ji.com/neutralizing__amplifier.htm

Although the article covers grounded grid amplifiers, if you scroll down the page you will see the section that covers "Grid Driven" amplifiers which is what the hybrid final amplifiers are. I highly recommend Tom's article as a must read for all members/hams.

Yes is ok like this Mark but as you know can be interesting to use RMT position on TS820 for frequency spot and in this scenary you will have R820 and TS820 in RX.

From: John Davidson
Topic: 41479 Message: 41511

I was starting with the carrier control set low so as to limit drive and IP initially, while quickly tuning the plate to a dip, praking the drive tuning and gradually , increasing drive with the carrier control until I have ALC action and finishing with alternately increasing load and re dip plate until I get 200 mA. So no strain on the tubes from overcurrent tuning up.
I am mostly on CW so don't have to change the mode switch when I am done tuning up. .The whole process takes me about 15 seconds to complete.
I grew up with tubes so peak and dip are not a new thing to me. No tune radios are still a novelty in my mind !

From: kd0fds
Topic: 41480 Message: 41512

hiya Fred.

Sorry I don't have any good photos of the pins on the counter boards, but I have taken mine apart many times!

unplug power from ts-820s. No need to go shakin' hands with mr. electricity.

Take off the top and bottom covers. (mind the speaker cable!)
Follow the leads from the actual display to a large goldish metal box on the top. That's the counter assembly. Big linear connector on top and there is another connector on the bottom. Clean those pins/connetors. Maybe that is all it will take?

OK. Same 9000? 4 screws hold that big box in the rig. Wait 'til you drop one of those 4 screws and it disappears in the wire loom. Don't panic. You'll find it eventually.

Now you have the little bugger in your hands. Start taking out all the screws in that thing too. The screws are all the same length so you can just drop them into your magnetic bowl.

Got the 2 lids off, eh? nice work. Screws in the corners of the boards right? Take those out. Now you can (gently) remove the boards from the box. The pull up straight off the internal interconnect pins. Feelin' extra proud of yourself? Pop the plastic pin holders from the metal box so you can REALLY get after the pins on the cleanup steps. I mean you don't want to have to do this twice, right? (or about 10x like I have.)

Assembly = no worries. You will find that the boards only go back in the box one correct way. If you notice the connector seems to stick out a long way, yeah, that isn't the right board on the right side!

26 screws later...and after pushing the connectors back on you are ready to fire up your rig an check that counter again.

Good luck.

If that doesn't work, check into "through hole" repairs. Basically, you will be soldering tiny wire strands through the through holes on the boards in place of the questionable solder only connections. You can't get to all of them, but there are about 24. I think the hole under IC#11 is a blind hole because the chip is on top of it.

If that doesn't work, get out a bright light and a magnifying glass and start looking for cracked traces. That is how I FINALLY fixed my counter. (image in the photo's section under kd0fds)

Since I've had my TS-830S for almost 30 years, my tune up procedure hasn't changed all that much. I generally tune for maximum power output viewing the inline meter (not the meter in the 830). When max power is achieved, I then check for final tank resonance (by checking or doing a dip of the final if necessary) and then making sure the ALC level is set properly according to the instructions. Any RF power lowering, as viewed on the inline meter, generally is insignificant on the other end of the contact. Keeping your final tank circuit happy by being in resonance is far more important for its components, tubes, etc. All of my components in the final and driver stages are still original and look like they were just put there recently. Although lower frequency operating tends to be less of a problem (tune for maximum output versus dip/load), it can be more stressful for components, tubes, etc. as you climb higher in frequency if the final is not in resonance. Checking/adjusting for correct neutralization of the final is always an important consideration.

My CE 100V and 200V, from the late 50's, were no-tune transmitters but it took several weeks to get them to work that way on all bands.

Topic: 41515 Message: 41515

Hi Kenwood members;

Could someone confirm me if the mechanical design and mechanical drive shaft behind the main dial of both Kenwood rigs are the same or not ?
I personally did not have a TS520,but regarding some pictures I saw before,I presume there are both quit the same and maby some pieces are interchangeable ??
I look forward if perhaps someone could give my some more details around.
I am chearching for a new mechanical drive shaft gear for my old TS515.

Regards Jean ON4AEF.

Pete,
I have a CE-100V here that was given to me. I just put it on the Bench.
I am going to completely go through it. It's been sitting somewhere for
many many years.

73,
Gordon

Thanks, Pete. I agree 100%. Keeping the final tank circuitry in resonance is much more important than the few extra watts you may get from simply peaking the RF meter. I personally think it plays not only a big role in the life of your components but also aides in the quality of signal you broadcast.

Thanks,

Rick/K5IAR

Subject: Re: [TS-520_820_530_830] Re: TS-820 - Dip or Peak?

Since I've had my TS-830S for almost 30 years, my tune up procedure hasn't changed all that much. I generally tune for maximum power output viewing the inline meter (not the meter in the 830). When max power is achieved, I then check for final tank resonance (by checking or doing a dip of the final if necessary) and then making sure the ALC level is set properly according to the instructions. Any RF power lowering, as viewed on the inline meter, generally is insignificant on the other end of the contact. Keeping your final tank circuit happy by being in resonance is far more important for its components, tubes, etc. All of my components in the final and driver stages are still original and look like they were just put there recently. Although lower frequency operating tends to be less of a problem (tune for maximum output versus dip/load), it can be more stressful for components, tubes, etc. as you climb higher in frequency if the final is not in resonance. Checking/adjusting for correct neutralization of the final is always an important consideration.

HI All,

I am wondering if the remote VFO for the 820 will function with the 520S? I am in search of a VFO to complete the station and thought this might be an option. Haven't had a chance to find the manuals to read it myself yet.

Thanks
Archie

Hi Tom,

I have an interest in the SP-230 if its a good match for my TS-520S.

Also maybe the VFO is it will interface with the 520....

Subject: [TS-520_820_530_830] Complete Kenwood Vintage Station for Sale

Good Evening Group:

I wanted to give my fellow members an opportunity to have a "Heads-up" prior to this equipment going onto eBay and / or other outlets for liquidation. If there is an interest in any or all of the units, please contact me, off the list to discuss further.

The items are as follows:

Kenwood AT-230 antenna tuner

Kenwood MC-50 dynamic cardiod desk microphone

Kenwood SM-220 Station Monitor

Kenwood SP-230 external speaker

Kenwood TS-820S Amateur HF Transceiver

Kenwood VFO-820 external analog display VFO

The units have been keep under dust cover, in a smoke free environment. The above are from my primary operating station, and were in use as recently as this past weekend.

tnx es 73 / 76

Hi Jon.
R820 connect to if ts820 loss part of signal so you must use very short coax cable.
Have you doid the remote cable ??
Have you only connected pin 4 R820 to pin 5 VFO connector ts820 ?
About other pin for RMT and trcv ????

My 100V was sitting by the curb waiting for trash pickup before I got it.
Took a lot of work to get that thing up and running. Had it on the air
for several years mostly on AM. Not bad for SSB either. I used my
Squires Sanders SS-1R as the companion receiver. I even had a QSO on 20
meters SSB with Wes Shum, the designer of the transmitter back in the
90's. Finally took it to Dayton several years ago to find it a new home.

Pete,
I love hearing stories like that. The 100V was way beyond it's time for
1957-58.
I'll let you know how the restoration goes on this thing.

Hi Roger,
You might indeed have a cap problem or a switching problem in the tank circuit. I have repaired a couple radios that did. I have a procedure up on my site that tests these caps for proper switching in and out of circuit. In order to get the tank circuit to resonate, the coil taps and additional ceramic caps are switched in and out, in a rather complicated arrangement, to get the right combination to resonate on the desired band. If anything is amiss, then no resonance, you can't tune it, and no or low power out.

The TS-515S operator's manual is available at the following link.

http://afu-df3iq.de/Hersteller/Kenwood/TR-515S_operating%20manual.pdf

It's difficult to say whether the tuning mechanism and mounting of the
TS-515S VFO is the same as the tuning mechanism and mounting of the
TS-520s VFO.

I suspect the VFO tuning range, 5.500Mhz to 5.000Mhz, in the same in
both transceiver VFOsbutI do not believe the mounting and electrical
connections to the TS-515S VFO are the same as the TS-520S. I have a
Kenwood R599 receive and it's VFO appears to be the samephysical design
as the VFO in the TS-515S, based on studying the top view of the TS-515S
chassis on page 18, figure 18, of the TS-515S operator's manual and
comparing that with thesame top view of the R599 receiver I have.
Assuming that's true then the TS-515S VFO mounting is not the same as it
is in the TS-520S and the electrical connections are soldered to the
TS-515S VFO verses using plugs in the TS-520S VFO. I can't so for sure
whether the physical offset from center whether the TS-515S VFO will
"fit" properly in the TS-520S or vice verse.

Problem I have the mechanical setup of my TS515 VFO is been wore out totally hier !!!
So I look for a change what kind of matter it should be.
So I thought by using the VFO of another naber type of radio,in worst case hi ..
But if someone nows a source where I possible can obtain anothe rone,always welcome..
Thanks for yoru information Mike.

Regards Jean ON4AEF.

Hello Jim,

Thanks for the response. I ended up replacing a choke and two ceramic caps. They apparently had been damaged by the last owner that had the radio operational.

When removed from the circuit, it was found that they (the caps) had apparently been cooked pretty good. They were way out of spec and probably had other issues (i.e. they were breaking down inside).

Thanks for the link, I will look at it for future reference. I am currently restoring the TS-520S that I previously didn't think was repairable. After looking at it more, it was just too nice to scrap for parts and I don't believe I will need to invest too much to get it working. Already have the receiver working (bad transistor for the carrier oscillator and VFO repair/tuning). TX looks like it is in good condition, except I need to replace some things I borrowed to fix the TS-820S).

Thanks again and 73,

Roger (AE3RT)

This was for you, Emilio. It is the pin connections for the cable between
the T599 and the R599.
I think the email was getting too long so I removed the rest! Is this what
you need?

I do not have a cable schematic. I did find the following information that
may be of help.

>
> >From the T599 manual I have, the following is the "REMOTE" pin
> assignments.
>
>* 1. - VFO input/output during transceiver operation

41533. Liquidating my Kenwood Station Equipment.

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-28 11:37:49 UTC
From: sceneryguru
Topic: 41533 Message: 41533

Good Morning Group:

If you saw my earlier post, you are aware that I am in the process of liquidating my Kenwood station equipment. To those members who took advantage of my offer to sale Thank You!. And to the entire Group, Thank You for indulging me.

The following units are unspoken for and are destined to go to auction this evening, Thursday, March 28, 2013. This is the equivalent of a "Last-Call."

Kenwood AT-230 antenna tuner 7.2 x 5.3 x 11.5 inches 7.5 lbs.
The Kenwood AT-230 antenna tuner covers the 9 amateur bands from 1.8 to 30 MHz. Through power is 200 watts maximum. It has power scales for 20 and 200 watts. Rear panel jacks: Input is SO-239 [UHF]. Antenna Output 1 is SO-239 [UHF], Antenna Output 2 is SO-239 [UHF], Antenna Output 3 is wire connection and ground. The AT-230 is compatible with the TS-520/30S series and TS-820/30S series.
"Quite possibly one of the best small tuners ever made"

Kenwood SP-230 external speaker 7.2 x 5.3 x 11.5 inches 4.0 lbs.
features filtration. There is a switch on the front panel to select input A or B. The headphone jack on the front panel is post-filtration. 8 ohms maximum input 2 watts. Compatible with all Kenwood models.

Kenwood TS-820S Amateur HF Transceiver 13.3 x 6 x 14 inches 35.2 lbs.
is designed for SSB and CW modes in the 160 through 10 meter ham bands. It also features receive of WWV at 15 MHz. Power input is 200W PEP SSB and 160W DC CW. (This transceiver does not have general coverage receive). The TS-820S can transceive with the Kenwood R-820 receiver.

tnx es 73 / 76

Hi,

What are the prices for tuner or radio?

73,

Hi
I am a new ham and am trying to set up my shack. I have a TS 520 and I am interested in your AT 230?. How much are you asking for it?
Thanks

Check your switches. I have one of these rigs but forget exact lay out.
however there is a rotary switch that indicated IP and a few others, slowly
flip this to see if all the meter readings go high.

Being a tube radio, you arent going to fry it as quick as you would with
solid state.

The rotory is labeled ALC IP RF and HV. I always ran mine watching either
the ALC or IP. There are two other knobs to think of also. Play with the
RF control as it will allow you to deflect meter to actually show you true
signal. RF knob will either wipe ou the noise or make it appear really loud.

Also what mode are you in?

Thats what I was looking for, I knew the RF knob controlled this, which most people arent familiar as they are use to a Squelch control, not knowing that is what RF gain does also, in a different manner.

In receive the meter is always connected to the S-Meter circuit. If the RF gain is turned CCW thee meter will read UPSCALE.

Turn the RF gain fully CW.

Thanks everyone. Backing off on the RF gain solved that problem. Now the next problem is the drive control does not move the meter when adjusting for peak. Is the load control minimum setting clockwise or counter clockwise? I am using K4EAA's tune up procedure.

Greg,

Looks like you already got your answer from someone but just in case you missed it, your RF gain control is likely turned all the way down. As you turn it down, the S meter goes upscale and will peg when the F gain is all the way off.

41548. illuminating AT meter?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-29 13:57:22 UTC

Topic: 41548 Message: 41548

Hi All,

Has anyone modified an AT-220 so it has a illuminated meter? Also maybe later the VFO I'll have soon.

My gear is in a low light condition and it would be neat if I could see the meter without going to an overhead light.

I am thinking that I could modify the unit with a 3V LED and small internal battery.

What would be real cool is a touch sensitive ON/OFF area on the face that had a burn time that I could program for say 5 or 10 minutes.

Can anyone lend some ideas? I'm not keeping the gear for resale, so I don't mind modifying it (in a clean manner).

TIA,
Archie

I have put lights in the meters of a couple of my tuners....done properly it does not affect the value of the unit in my opinion....both of the units I did it looks totally factory...I spend a few hours in my radio room and do not always like lights glaring at me so illuminated meters really help keeping an eye on things....plus as you get older....subtle illumination sure helps....I put meter lights such as the lamps in the radio's in mine and run things with a wall wart....but your idea of led's is good.....they draw so little power that an internal bat...would last a long time....touch switch....never thought of that....should work....maybe RF might mess with that ?....I used mini rockers on the side of the tuner just behind the front trim ...they are very small....and look ok....good luck on the mods.....some of these simple mods can be a lot fun with excellent results....

Regards....Wes...VA6DWH

I just did my AT-230 with blue LED's. Just due the math for the resistor or resistors. Installed a jack in the rear for the power. I may add a pot for more lighting control too!!!??? Not sure yet.

Subject: [TS-520_820_530_830] illuminating AT meter?

Hi All,

Has anyone modified an AT-220 so it has a illuminated meter? Also maybe later the VFO I'll have soon.

My gear is in a low light condition and it would be neat if I could see the meter without going to an overhead light.

I am thinking that I could modify the unit with a 3V LED and small internal battery.

What would be real cool is a touch sensitive ON/OFF area on the face that had a burn time that I could program for say 5 or 10 minutes.

Can anyone lend some ideas? I'm not keeping the gear for resale, so I don't mind modifying it (in a clean manner).

TIA,
Archie

I am interested in that as well.

For my TS-820S, I put a few white SMT LED mounted on a set of two parallel wires and put that right on top of the meter. The effect was great. I've not pulled my AT apart to look but I think that would be workable there as well. It's also a modification that would be reversible assuming the top of the meters were exposed.

I changed the RL-1 relay and it works fine on SSB. However, when I switch to CW and insert the key (even just a plug) it engages the sidetone and mutes the RX, but doesot key the transmitter; Closing the key sends CW. What might be happening ... this has me stumped?

Topic: 41555 Message: 41555

Hello to all. I have an MC-50 mic that was gifted to me with out a cord. I can make a cord and have plenty of the 4-pin connectors for the radio end of the cord but I do not have the 5-pin connector for the Mic end of the cord. It is a 5-pin with the 5th pin in the center of the connector. Does anyone know where I can obtain a 5-pin connector for the MC-50? I would even take a used one as long as it is still in good shape.

Thanks

Dan,

Good luck locating them as those 5 pin MC-50 connectors, both the chassis and cable end, are "unobtanium". Many have been searching for a long time and have come up empty handed. If you do manage to find a source please let us know.

Sometimes you will find somebody getting rid of a MC-50 base w/cord when the mic has died or been damaged. I would grab it.

G'day,

Another way of doing it is powering from radio using a RCA plug and socket so as you turn your radio on it automatically turns tuner lights on. From 12.6v secondary tap on the transformer to an RCA plug on rear of radio then also RCA plug on rear of ATU, work out using ohms law appropriate resistor to suit your brightness level for led. Only issue is working out how to mount the led\lamp over the meter in the ATU.

41559. KENWOOD HYBRID USER NET (March 30th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-30 20:39:30 UTC
From: mvgilger
Topic: 41559 Message: 41559

The Saturday's net on 40 meter we had 23 stations checking with good band conditions. There were 2 new stations checking in. Out of those, there was:

6 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

There will not be a Sunday's net on 20 meter due to it being Easter unless someone wants to step up and try their hand at running the net. Wish everyone a nice Easter and hope to see everyone on the net next week.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 135, Sunday's total =39 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hello

I have a ts 520 here that someone tried to do a modification to. I will try and describe the problems that I have and maybe this is something that you have seen before and maybe there is more that I have not found.

Anyways

There is an orange wire that goes from the antenna relay terminal 12 as far as I can tell that is spliced to a yellow wire that goes to the mode switch. The best that I can tell is that the yellow wire from the mode switch is supposed to go to car unit board "CWR" terminal??? What about the orange one???
There is a grew wire with a white tracer that was cut and is laying by the VOX board and IF unit board. Where would this wire go???

There is a brown wire on the IF board that is connected to the "CW" terminal and then back to the mode switch. This does not look like it would have come from the factory. Is that right? I looked at the schematic and it does not as far as I can tell show a wire hooked up to that terminal.

There were also a pair of green wires cut from the mode switch that are soldered together. I think I know where these wires go on the mode switch.

As far as the mode switch goes is there a schematic of it??? I have looked all over and have not had any luck. How do I know where the wires go??

Thanks for reading and helping

41562. SM-220 and TS-520S Pan Adapter IF

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-03-31 17:14:53 UTC
From: n3kvl
Topic: 41562 Message: 41562

All,

I am adding the IF tap to my TS520S.

I added the 10K Ohm resistor and 22pf cap as in the manual and an RCA to the back of the radio.

I used RG-174 coaxial, however the manual notes it as 75 Ohm although all spec sheets note it as 50??

So, with the SM-220 connected to the rig..

I can see the marker of the adapter, but not the 25Khz calibration from the radio, and I can not hear the adapter marker in the rig.

A couple of things...

I can not peak T201 as noted in the manual as I do not have the adjusting tool. Can anyone tell me what tool? I've seen them, but can't remember where.

Also, could the 50 Ohm RG-174 I used be a problem? Also, I did not have an RCA jumper with coax, so I used an audio cable. Is this a problem maybe.

Also, I only had a 22pf mica cap rated for 600V. From what I have read this should not be the problem but maybe it is??

Also, The schematic and pictoral of Q4 is a little strange and I hope I tagged onto the drain properly. I did move the connection to the capacitor C35 because it seemed like I could identify the drain lead correctly by tracing it position versus looking at the diagram of the transistor in the manual and the case of the rather small real one on the board.

Basic questions, but I am just gettting started with actual hands on bench work.

Any advice would be appreciated.

Did you verifythe correct Band Scopeis installed in your SM-220?

There are 2 Band Scopes for the SM-220

1. BS-5
2. BS-8

The correct Band Scope for the TS-520 is the BS-5.The BS-8 will not work
with the TS-520.

"Is the unit marked?"

If you mean is the SM-220 marked whether it has a band scope module or not then the answer is typically "No". The band scope modules (BS-5 and BS-8) are "optional" accessories for the SM-220. This is clearly stated on page 18 section 8.1 titled, "GENERAL INFORMATION" in the SM-220 manual. Just because there's a 3.5mm socket on the SM-220 panel doesnot mean a band scope module is installed. It's up to you to determine whether a band scope module is installed or not. Remember, the correct band scope module for the TS-520 series transceivers is the BS-5, the BS-8 band scope module will not work with the TS-520 series transceivers.

The following link shows what the band scope modules looks like and how one appears when installed in the SM-220:

http://www.coutant.org/sm220/

The band scope module should have a stamp on the edge indicating which
band scope module it is.

I also see from the manual I made a error in selecting the IF take-off point. It is from the NB board, not Q4 on the IF board??

41571. Re: [TS-520_820_530_830] SM-220 and TS-520S Pan Adapter IF

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-01 19:51:55 UTC
From: Mike
Topic: 41562 Message: 41571

The Band Scope has to be placed in the receive signal path where the
bandwidth is the widest. That is why the Band Scope is connected at the
NB and not any of the IF amplifiers. If you tap the IF stage "after" the
crystal filter then the Band Scope would be useless because at that
point the crystal filter has filtered all but 2.5 or 3Khz of the receive
signal. The same applies to the NB.

Hello fellow members. I have a unmodified working TS-830s and a set of 599D Twins with matching speaker . the 830s has a MC-50 Mic and the 599D's have a D-104 mic. the 599D reciever also has the 2mtr module installed. I would like to know what the members think these are worth as I don't want to overprice them but at the same time don't want to be lowballed into giving them away. They are both excess to my needs and I would ask that you reply thru e-mail and not the reflector to keep from clogging it up with unnecessary info.
thanks
Eldon Scott

Hi Alan,

Over the past month or so I have fooled with the TS-520se trying to pin down this issue. I've poked and wiggled all of the connections and terminals on the RF, IF and generator boards. I've actually poked just about every one in the entire unit, but nothing seems to make a difference. After a random amount of time everything just goes back to normal, and then after a short time it starts doing it again.

It seems to be doing it more frequent now. I'm nervous to event attempt a qso on it. Can you think of any other things I should look for?

One other clue, when this is happening if I turn the RF gain fully CCW, the meter only goes up to around 1/3 of the full meter (http://content.screencast.com/users/Tyler81/folders/Jing/media/1253a282-fe21-4f48-8288-0b171fd729b1/00000812.png). When the problem stops (I can send/receive again) the meter peaks when I turn the RF gain all of the way CCW.

Thanks for any help,

Tyler
k7fru

I don't see where you tried cleaning relay RL-1located top left rear
below the Marker and VOX Unit boards. You might try doing that then
check to see if the symptoms change.I don't know if relay RL-1's cover
can be gently pried off or not but if it can be then you might try
cleaning the relay terminals with a thin piece of paper wet with contact
cleanerslid between the relay contacts. Clean the relay socket as well.
This requires "gentle" prying off of the relay's cover and "gentle"
passing of thin paper wet with contact cleaner between the relay
terminals. You will have to "manually" move the relay's armature with
your finger to clean some contacts.You should use several pieces of
paper wet with cleanerslid through the contacts until the paper is no
longer "black" from carbon. I use simple printer paper cut in thin
strips that fit between the relay terminals. Thoroughly inspect the
relay terminals and armature movement to ensure the relay terminals are
not bent after your cleaning process. Use canned air, available at
Walmart, to remove any/all cleaner residue. Adhere to ALL warnings
printed on the cleaner's label. Some cleaners are flammable and it only
takes a small spark to ignite the cleaner so don't ignore or skip
reading the warnings on the cleaner's can!

Relays are one of the most "ignored" or "overlooked" component in the
transceiver. Quite often relays are only "visually" inspected to see if
the armature is moving when the relay is energized. If the armature is
moving then the relay is "assumed" to be "okay". Just because a relay's
armature is moving when the relay is energized does NOT mean the relay
"contacts" are good! Over time, carbon builds up on the relay terminals
due to circuit switching. Carbon build up on relay terminals can result
in intermittent connections or no connection at all.

41576. ?Anyone for an 820 repair challenge?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

I have a really nice 820...stopped working. Finals and driver are fine, but the xmit/receive will start and stop as if the radio had a mind of it's own. Last time radio stopped working, it would not come back.It has been modified by the last owner. It has a mysterious pcb in the radio, and also has receive on 17 meters in the aux slot. I am unable to diagnose the issues. Looking for someone to repair the radio for me. Will ship and will, of course, pay for repair. I am in Maine.Please respond to hanson1448@...m if at all interested.
tnx,
de ke1lg

Thanks to all who inquired. the 599D's have been sold.

> Hello fellow members. I have a unmodified working TS-830s and a set of 599D Twins with matching speaker . the 830s has a MC-50 Mic and the 599D's have a D-104 mic. the 599D reciever also has the 2mtr module installed. I would like to know what the members think these are worth as I don't want to overprice them but at the same time don't want to be lowballed into giving them away. They are both excess to my needs and I would ask that you reply thru e-mail and not the reflector to keep from clogging it up with unnecessary info.

Hi Tyler,

I was wondering how you had made out with it. Sorry to hear you are still having a problem. Let me study the schematic for a while and I'll get back with you.

Alan, KD5R

Subject: [TS-520_820_530_830] Re: ts520se sidetone question

Hi Alan,

Over the past month or so I have fooled with the TS-520se trying to pin down this issue. I've poked and wiggled all of the connections and terminals on the RF, IF and generator boards. I've actually poked just about every one in the entire unit, but nothing seems to make a difference. After a random amount of time everything just goes back to normal, and then after a short time it starts doing it again.

It seems to be doing it more frequent now. I'm nervous to event attempt a qso on it. Can you think of any other things I should look for?

One other clue, when this is happening if I turn the RF gain fully CCW, the meter only goes up to around 1/3 of the full meter (http://content.screencast.com/users/Tyler81/folders/Jing/media/1253a282-fe21-4f48-8288-0b171fd729b1/00000812.png). When the problem stops (I can send/receive again) the meter peaks when I turn the RF gain all of the way CCW.

Thanks for any help,

Tyler
k7fru

Well, from the sounds of it, its probably nothing very complicated. Bad switches and relays come to mind as do loose connectors. It's possible that it might be something wrong with the carrier board - they always seem to have some kind of problem if not adjusted in a while. And it could well be a power supply problem, also not uncommon.

What are the characteristics of the failure? Do you get any noise from the speaker at all? Does the meter needle move?

I assume this situation was the case for all bands and modes?

Let us know!

Steve,

  I tend to agree with Mike. The relays have gone through thousands of cycles during their life...they can and will cause the problem(s) you state.
Both can be removed and, the contacts cleaned, as stated. I have "fixed" numerous problems on the 820 series by cleaning BOTH relays. Just do
one at a time..and retest.

  If I may suggest..IF you plan on keeping this rig for a long time...invest in 2 new..or known good relays and, 1 known good driver and,
one pair of known good finals. Not to mention some DEOXIT and "canned air."

41581. TV502/506 Cables

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-05 01:33:03 UTC

Topic: 41581 Message: 41581

I have a couple of questions about this (TV-502/506) connecting cable. I understand one of them (the 502, I think) has a pigtail with a RCA plug on it. Does this mean the cables for the two transverters are different? Needless to say, these cables are not available or I haven't been able to locate one, so, I need to make them. Can someone suggest a cable type to use and where I can find it?

I'm not quite ready to start building the cables I just want to get all my ducks in a row.

Thanks,

Rick/K5IAR

Hi Terry,
Haven't talked to you in a while. Hope you're doing ok. I can tell you that you are missed on the Yahoo group.

I have an 830S that was in pretty bad shape, with a med amount of corrosion. It had all kinds of problems in receive that I have pretty much worked out. There were some bad 3SK73's, and I actually found a source for them. It has an ALC problem. I can get an almost decent reading, but it immediately starts to drop. Even with a new driver tube, it drops the same. I've seen several that do this, but they drop slowly. This drops very quickiy. I think the ALC level might be ok if it didn't drop down. It does stabilize, sort of but at a low level. It's usable on the lower bands, 15M and down, but the CAR is set at 9-10 or above on 15M. I have to set the CAR at too high levels on all the bands, from about 5-6 on 180M to 9--10 on 15M. On 24 and 28 I can't even get an ALC reading. I have rebuilt the B/Sw and that seems to be good. All driver coils have an affect when adjusted. I can put the VTVM on the driver out and get decent level, with both the drive and coil adjusts affecting level on all bands. 49-50v seems to be where the ALC starts to work. Not sure, cause my VTVM is not accurate.

This one is driving me crazy, I can't find anything. If you have any ideas, I would appreciate it.

Best,
Jim

Hi Jim: I am doing fine.

Well lets start with your VTVM.
1. Do you mean you are using a 11 meg ohm input VTVM and a single germanium diode RF probe to measure RF drive levels? If so, inorder to run Tx Level Diagrams you need 2 different RF probes. One with single diode and one with multiple diodes. Cant use a single diode probe to measure output of 12BY7A Driver tube as RF drive voltage will exceed PIV of diode and wreck the probe. May even be a problem on control grids of the 6146 finals. Should be pretty easy to cal your VTVM to get reasonably accurate readings. Not sure what issue is here.

2. I use a Boonton 92E RF Millivolt meter or an O-scope to run TX Level Diagrams. I also have a HP-410C VTVM which I use to measure ALC/AGC bus voltage as it has over 100 Meg input Z and wont pull down the voltage. It has the factory AC/RF probe which can be used for RF drive measurements, but I prefer to use the Boonton.

3. Quick refresher on how you get ALC indication while loading the rig. Need sufficient RF drive level to 6146 control grids to overcome the dc operating bias offset. When this occurs grid current flows on positive peaks of the RF envelope. This current flows thru FG lead back thru base bias resistors of ALC amp Q19 on Audio Board turning it on hard. Q19 is hanging on the ALC bus line and acts like a variable load resistor. This bus is high impedance and cant stand any load on it. When Q19 turns on it pulls the ALC bus line down from 3.6vdc to approx 2.6vdc. The ALC bus voltage is fed to Gate 2 of TIF amp Q29 on IF board. Lowering the control voltage to Gate 2 of Q29 reduces the TIF signal output level. Lowering TIF level lowers RF drive to the TX Mixer on RF board.

The ALC meter is a FET based reverse reading voltmeter monitoring the ALC bus line voltage. With 3.6 vdc on the ALC bus the meter reads zero. The minute the ALC bus voltage starts dropping from 3.6vdc the meter starts moving up scale. FSD will be at approx 2.7vdc on the bus.
Ignore the black rectangular ALC box when loading the rig. It has absolutely nothing to do with loading the rig. Set Car Pot to give yourself a good indication to peak the Driver tube grid and plate tuned circuits to resonance. I usually do that around 2/3 to 3/4 full scale. If indication pegs just reduce CAR pot to get needle off the peg.

6146 TX operating bias is approx -62vdc. Need grid current to flow on positive going peaks of the RF drive level to produce ALC indication. 44 rf volts x 1.414 = 62 peak RF volts. So with 44 RF volts of drive on control grids of 6146 final you will have just reached the operating bias offset and no grid current will flow and no ALC indication. At approx 49 Rf volts you will have max grid current and max ALC indication as you will have driven the 3.6vdc ALC bus voltage down to approx 2.7 vdc.

4. No ALC indication on 24mhz and 28mhz means you do not have RF drive level over approx 44 volts. You can verify that by measuring RF drive level at 6146 control grids. Now question is why and if have good Driver tube the usual reason is bad bandswitch contacts on the RF board. May see some peaking action on Mixer and Drive coils but not sufficient due to high

resistance band switch contacts.

5. As to Car Level. I would measure it at CV terminal Conn 8 Pin 1 and run pot thru its range and make sure you have 0 thru 9vdc. Then get on Cathode of D30 Balanced Modulator Diode with a mini-grabber and measure Car Level voltage there. Should be 0 thru approx 0.60vdc and stable to forward bias the diodes. If voltage is sagging here then Carrier output from Balanced Mod will drift low during key down. This is very unlikely but easy to check.

6. Next measure and monitor TIF signal at IF board Conn 6 Pin 3 and at RF board Conn 7 Pin 2. Again I would use O-scope for this. It should be approx 15 mv rms or approx 44 volts P-P.

7. Next measure output of TX Mixer on RF board at TP-4. Should be approx 2.5 to 3.0 rf volts. Much higher levels is a problem.

8. Next measure Driver tube output at Plate or at DRV terminal. Should be approx 55 to 65 RF volts. Service manual shows 77.5 but I have never seen one that high. I think highest I have ever measured was 68 rf volts.

9. Lastly measure rf drive at 6146 control grids Pin 5. Should be approx 48 to 49 rf volts.

10. Might want to measure/monitor dc bias voltage on 6146 Pin 5 key down as well. It should be approx -62vdc and not moving around. If it goes slowly lower then will require more RF drive voltage to overcome the higher dc offset. If it is drifting down need to troubleshoot -C and I would start by cleaning bias pot.

11. Lastly there is one trick you can do. Connect approx 3 vdc from your bench supply or two flash lite batteries to ALC bus. This temporary low Z power supply will hold the ALC bus voltage up and not allow it to control the TIF amp. Then run your TX Level Diagrams and see if you have normal rf drive levels that do not fall off key down. If you do then it tells you there is a problem with the ALC bus line. Something is pulling it down. If RF drive falls off at some stage with ALC defeated then you need to troubleshoot that stage by taking DC operating voltages.

I guess what I am saying is monitor RF drive levels with RF Millivolt meter or O-scope at TIF to the Finals and see where the level is falling down.

Sorry so long suggest we take this off list if need to continue troubleshooting.

Jim : Clarification Step 10. I meant to say if the bias voltage drifts higher or more negative then it will take higher level of RF to produce ALC indication. For example -65vdc bias requires more RF drive than -62vdc bias. 65/1.414 = 46 rf volts. Need greater that 46 rf rms volts if operating bias drifts from -62 to -65 key down.

hi Rick,

I added the rca pigtail to the cable that came with
my used tv-506, center pin to pin #5 on the transverter
plug and shield on rca cable to pin #12 on the plug.

I just disconnect the pigtail and put a short piece of
tubing over the end so it don't short out on anything
when I use the tv-506.

the cables are identical except for the 2m pigtail.

I used some thin coax and an old serial cable to make up
the cables.

I have the 12 pin connectors on ebay, search for kenwood transverter.

Hi All,

I need a source for the DC out connector for my TS-520S.

And a recommendation on a good solder RCA connector source.

Thanks

The power cord from an old Remington electric shaver works perfectly. Be sure to observe polarity.

Hello Folks,

I know what neutralization is and what this is attempting to accomplish.

I just brought a TS830 back to life with recaping the power supply and so forth along with recaping the RF final cage. Radio works great with outstanding reports on audio quality and with Rf output @ 115 Watts with a new 12BY7A driver and new 6146B tubes.
On the subject of neutralization of the 6146B tubes when replaced. With reference to the Kenwood instruction manual and using a RF volt meter, of which I don't have, Plan B is to use external receiver, both the TX and RX tuned to 28.5 mhz using a dummy load on the transmitter and the SG switch in the On position and adjusting the TC-1 control - I can't get a minimum S meter reading on the external receiver - in fact - no change at all.
So what I did while adjusting the TC-1 control - monitored the output and saw an increase in power of about 1 - 2 watts.
As mentioned, the radio works as it is supposed to and love the older technology as I am also old.

Any suggestions would be greatly appreciated, love the hobby as I do and all the operators.

Mike,

Congrats on your accomplisment so far. I have not been successful using the secondary receiver method either.

If I may suggest: buy orbuild a simple RF probe for use with a DMM...or obtain an old fashioned VTVM and build a probe for that..you
will be glad you did as, it's/their use is needed for various alignment steps and, is just handy to have around Some guys use o'scopes.

I am not positive but, I do not think you will be able to observe a "null" using the procedure you described. The "SG" switch should be OFF. Also, how far apart
is the second receiver and the rig under test? You may have to move it closer. For this step, I built a simple "dummy load" out of a single 1 watt non inductive resistor
wired to a PL-259 plug and use a test lead with two "mini-grabbers, the RF probe is built into one of the "grabbers."

You can build an RF probe for less than $1.00 - $2.00 not counting housing.(old pens are free.) There are numerous plans out there

I too would be interested in 2 of these red LED segments version. I have two defunct DG-5 waiting to come back to life...

I have been using the C520 (http://www.aade.com/C520/C520.htm) for the past 6 years and it has worked well. But would prefer a more "original" version with my Kenwoods.

Hi Bart,

If you can't get a RF board locally so too speak. You might try the web page: hifissb.com This group is from the UK and I just recently ordered out an audio board for a TS830 that went up in smoke. These folks deal in surplus radio equipment boards and so.

Hope this helps.

Butch,

It can be done, I have done it to both of my 530's and just removed it from both only due to other issues I had to find and correct, that wasn't related to the IF ports. The pan display works well, but it does tend to desensitize the radio by about 6db, my sensitivity increase by 6db when I uninstalled the mod without undertaking the RF board alignment procedure. When installing the IF2 port (to monitor incoming audio\CW patterns) the display is distorted. A good friend of mine is helping me with another issue at the moment and once this has been sorted will be trying out a new take off point for the IF ports thzt he has worked out. The modification is for the 8.803MHz reference (BS8).

41604. KENWOOD HYBRID USER NET (April 7th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-07 18:29:54 UTC
From: mvgilger
Topic: 41604 Message: 41604

The Saturday's net on 40 meter we had 16 stations checking with good band conditions. There were 2 new stations checking in. Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 9 stations checking in under very poor band conditions. We had 1 new check-in, WB4ODM

Out of those, there was:

4 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
3 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

OK I am getting s little lost in this rig. I received a ts 520 to use as long as I want to but I have to get it running. He told me there was a mod done to make it run on am. I think I am close and maybe my problems are all linked.

I have nothing coming out of the speaker when I put the rig into cw mode. I can send a cw carrier but I have to have the rec/send switch in the send mode.

When I am on USB/LSB all I get of the speaker is white noise on all bands.

If I press the WWV button then I can hear the time, airplane weather reports and some cw. The s meter actually moves!

I tuned the rig on a dummy load and get 100+ watts out on 80, 40, and 20 but only get about 50 out on 15 and a little less than that on 10.

I really want to get this on the air and do some cw work!!!!

Thanks

Andy

Andy:

The good news is that a common problem with the TS-520 is that when you switch on WWV the switch does not come back all the way when you switch off, leaving the rest of the bands seemingly inoperative in receive. So try putting a little (teeny tiny), CRC QD Electronic Cleaner, LPS-1, or Deoxit on that switch and work it back and forth (DO NOT USE WD-40, LIQUID WRENCH, PB BLASTER, or CRC LECTO MOTIVE CLEANER!)

The bad news is that "mod done to make it work on AM" probably means it has been converted for CB use and that entails some changes to the IF board and other boards.

So try cleaning the WWV swicth frist and see what that does for you.

Lower output on 10M is not uncommon.

Good Luck!

41611. TS-520S Cathode and Screen Resistors

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-08 19:38:22 UTC
From: n7bes
Topic: 41611 Message: 41611

This is my first post so please bear with me, I did some searching through the previous threads here and couldn't easily find exactly what I was looking for.

I have a TS-520S that is not putting out what it is supposed to (only getting about 40 watts out). After a bit of digging found that the final cathode and screen resistors were cracked/blown. I bought one of the resister kits from one of the hybrid repair guys for the common final resistors that get burned out when someone goofs up (prior owner ran full power with bad coax... couldn't figure out why he kept popping fuses until he found the bad coax). So I now have 2 questions....

1. I was able to easily replace the 10 ohm and 100 ohm cathode and screen resistors. The resistor kit I got also comes with a 470 ohm 1W 5% resistor. After looking over the final as well as the schematics, I am not sure where this is supposed to go. Can anyone shed some light on where this resister is intended to go?

2. After replacing the 10 and 100 ohm resistors (and a proper tune) I am still only getting 40-50 watts into a 50 ohm dummy load. After further review I am finding mention that if the resistors are blown that it may be necessary to replace C7, C8, and L1 in the final as well, so I have ordered a kit with these 3 parts from the same vendor. So the question is is this the best next course of action? Anything else I should be replacing? (already have a fresh set of tubes in) If this doesn't work what is the next step? full re-cap? or?

Thank you,
Bryan

Robert

Thanks for the reply and I will try that tonight. Is there anywhere I can find out what someone could have done to get the am mod to this rig?? I have spent the last few days on Google looking for answers but have not been able to come across any answers on how the cb mod is done: Some people say just replace a few crystals and others say it is a big job to get it done.
I would like to try and work it backwards as I believe I have most of the shings at least the easy ones done. I have spent hours looking at the schematic and should know this rig inside and out when I am done!!!!

Thanks

Bryan,

  It is either R-5 or R-6, can't remember which, on the RECTIFIER BOARD. I suggest "metering" them out first. If within specs..you can leave them alone...unless you just have to replace them.

Replacement of C-7, C-8, and/or L-1 is NOT automatic if the aforementioned resistors have blown.

 I would first: obtain KNOWN good set of finals and driver tube. Then re-run your tune-up procedure. Those parts can take quite a bit of punishment.
Testing final amplifier tubes in a "tubes tester" will show you if it is shorted...etc..etc....but it will NOT tell you if it will properly function in the "real RF environment."
That's one reason to stay with factory specs for wattage on the screen and cathode resistors...they blow first!
The previous "owner" may have "adjusted" some of the coils. Check the ""basic" alignment in the operators manual, including "neutralization."
Check your HV (high voltage). you can do this via the front panel meter. put meter select switch to "HV" flip send switch to SEND, read meter.
You should see 850 to 900+ volts, much less indicates a possible failure of one or both HV caps.
When properly tuned up for "full power,"...you should see about 800 volts, Ip of approx 225 and about 100 or so watts (if watt meter used.)

I won't get into the re-cap vs not to re-cap issue

Bryan,

What steps have you taken that makes you think you should replace C7, C8, and L1? What evidence have you found that identify those 3 components as the source of your low RF output problem?

Have you checked the 520's alignment using the service manual? Are the driver and final tubes good? Do you have a spare know good driver and pair of final tubes you can swap to verify it's not the tubes? Have you checked the Rectifier Unit's voltages to ensure they are correct?

Those steps should be taken FIRST before ANY COMPONENT(S) is/are replaced!

Tyler, I really haven't been able to come up with anything specific from looking over the TS-520SE schematic. I think I would next compare the power supply voltages leaving the FIX CH AVR unit under both normal conditions and when the rig is acting up.

Obviously there are many points on the boards themselves where DC voltages could be measured and compared either with voltages measured under normal conditions or with the schematic values but if you could get your hands on an oscilloscope it would make locating the problem a lot easier. Whatever is causing your receive problem is also causing your transmit problem.

I am still leaning toward a bad connection somewhere in the shared circuitry. If there are any socketed components, wiggle them gently. Press lightly on soldered components.

Subject: [TS-520_820_530_830] Re: ts520se sidetone question

Hi Alan,

Over the past month or so I have fooled with the TS-520se trying to pin down this issue. I've poked and wiggled all of the connections and terminals on the RF, IF and generator boards. I've actually poked just about every one in the entire unit, but nothing seems to make a difference. After a random amount of time everything just goes back to normal, and then after a short time it starts doing it again.

It seems to be doing it more frequent now. I'm nervous to event attempt a qso on it. Can you think of any other things I should look for?

One other clue, when this is happening if I turn the RF gain fully CCW, the meter only goes up to around 1/3 of the full meter (http://content.screencast.com/users/Tyler81/folders/Jing/media/1253a282-fe21-4f48-8288-0b171fd729b1/00000812.png). When the problem stops (I can send/receive again) the meter peaks when I turn the RF gain all of the way CCW.

Thanks for any help,

Tyler

Joe,

Thank you for the reply, I will check R-5 and R-6 on the Rectifier board the next time I crack the case open. The 4 resistors on the final board were definitely blown (physically cracked and out of spec on the meter) so they were replaced.

One thing that I forgot to mention (and part of what led me down the path of C-7,C-8,L-1) was that while tuning IP current fluctuates, once tuned it will start around 225 mA when I flip the send switch and then drop, over the matter of a couple seconds to 150 mA. Some information I had found online suggested that these may be the issue (especially if it is known that the resistors popped). Output power also fluctuates with the plate current.

I did replace the tubes (all 3) with what were supposed to be a "known good" set, but I have no way of truly confirming that, is there any way to confirm short of finding someone else local with a hybrid and talking them into giving the tubes a spin in their rig?

And I definitely stayed within factory spec for the resistors, I was aware that they are essentially sized to be fuses of a sort.

I will look into doing the alignment/neutralization procedure, I do know that the prior owner did not make those adjustments (prior owner is my grandfather).

On the HV reading, I am currently (after tune-up) getting 750 Volts on the meter when set to HV. Is this far enough off to suspect the HV caps?

Thank you again for taking the time to respond.

Thank you and 73s
Bryan

Hi Mike,

Thank you for the response. I forgot to mention in the first email, what led me down the path of C7, C8, and L1 was that IP current fluctuates, once tuned it will start around 225 mA and then drop, over the matter of a couple seconds to 150 mA. Some information I had found online suggested that these 3 may be the issue (especially if it is known that the resistors popped which they physically did)

I will look into doing the alignment process. I have switched out the tubes with a set that is "supposedly" known good, but I have no way of confirming, I do get similar results with both tubes (the new set does get me 5-10 watts more than the old set did, so 50-60 watts instead of 40-50 watts)

I will also check the rectifier voltages.

Thank you and 73,
Bryan

Hi Mike and Alan,

Thanks for the help. So far I have checked RL1 and RL2, both are seated well and appear to be brand new (I did not attempt to clean them yet though).

With the help of another ham, I believe I have the problem pinpointed to a bad zener diode on the FIX-AVR board. I am picking up a replacement tonight and will hopefully have this problem resolved. If so I will let the group know the solution in case anyone else runs into the problem!

73!

41626. Headset for TS-520s

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-09 15:34:48 UTC
From: dscolson1949
Topic: 41626 Message: 41626

Hi,

Can someone point me to a headset that is compatible with the TS-520S

Thanks

Dave KB1WOD

Bryan,

I know a couple of guys will beat me for this...but.....if you have, or are going to have, the replacement parts for the ones you suspect
may be faulty...replace them.

Inspect around the 12by7a driver tube socket...and the final tubes...for poor or "dry" looking solder joints. With magnification and bright light helps.

The 750VDC is too low. Measure the output of each HV cap...with a DMM/VTVM ...be careful there's lot's of HV there that will SK you. Compare the "resting/receiving" HV with the HV you get at full power and key down...should be usually no more that 10-12% drop...or as some say "sag."

Another check or two, is to tune up for full power(into dummyload), ..meter select switch to "RF" ...key rig...falling output usually indicates failing driver.

meter select switch to "Ip"...key rig.....usually indicates failing finals.

These are just some basic tests...but..helps narrow things down.
Does the fluctuation of the Ip happen on all bands or just one or two?

Subject: [TS-520_820_530_830] Re: TS-520S Cathode and Screen Resistors

Joe,

Thank you for the reply, I will check R-5 and R-6 on the Rectifier board the next time I crack the case open. The 4 resistors on the final board were definitely blown (physically cracked and out of spec on the meter) so they were replaced.

One thing that I forgot to mention (and part of what led me down the path of C-7,C-8,L-1) was that while tuning IP current fluctuates, once tuned it will start around 225 mA when I flip the send switch and then drop, over the matter of a couple seconds to 150 mA. Some information I had found online suggested that these may be the issue (especially if it is known that the resistors popped). Output power also fluctuates with the plate current.

I did replace the tubes (all 3) with what were supposed to be a "known good" set, but I have no way of truly confirming that, is there any way to confirm short of finding someone else local with a hybrid and talking them into giving the tubes a spin in their rig?

And I definitely stayed within factory spec for the resistors, I was aware that they are essentially sized to be fuses of a sort.

I will look into doing the alignment/neutralization procedure, I do know that the prior owner did not make those adjustments (prior owner is my grandfather).

On the HV reading, I am currently (after tune-up) getting 750 Volts on the meter when set to HV. Is this far enough off to suspect the HV caps?

Thank you again for taking the time to respond.

Thank you and 73s
Bryan

>
> I have a TS-520S that is not putting out what it is supposed to (only getting about 40 watts out). After a bit of digging found that the final cathode and screen resistors were cracked/blown. I bought one of the resister kits from one of the hybrid repair guys for the common final resistors that get burned out when someone goofs up (prior owner ran full power with bad coax... couldn't figure out why he kept popping fuses until he found the bad coax). So I now have 2 questions....
>
> 1. I was able to easily replace the 10 ohm and 100 ohm cathode and screen resistors. The resistor kit I got also comes with a 470 ohm 1W 5% resistor. After looking over the final as well as the schematics, I am not sure where this is supposed to go. Can anyone shed some light on where this resister is intended to go?
>
> 2. After replacing the 10 and 100 ohm resistors (and a proper tune) I am still only getting 40-50 watts into a 50 ohm dummy load. After further review I am finding mention that if the resistors are blown that it may be necessary to replace C7, C8, and L1 in the final as well, so I have ordered a kit with these 3 parts from the same vendor. So the question is is this the best next course of action? Anything else I should be replacing? (already have a fresh set of tubes in) If this doesn't work what is the next step? full re-cap? or?

I agree with Joe, follow his voltage and physical inspecting checks.

You can calculate the transmitter's actual RF DC input and output power by using some simple high school math formulas and the meter indications staring you right in the face every time you tune the transmitter!!

You have to calculate the DC input power firstand that's done using the following formula:

HV x IP = DC input power

For example, lets say the transmitter is tuned up to full power output. Using the above formula and the HV meter reading is 775VDC and a cathode (IP) meter indication is 220ma, at full output, what's the final amplifier's DC input power?

775 x .220 = 170.5 watts

Next, you calculate the power output at the rear antenna SO-239 connector. Since the average efficiency percentage of the Class AB1 final amplifier in ALL Kenwood hybrids is 55%, we simply subtract 45% from 170.5 watts and we get

170.5 - 45% = 93.7 watts output at the rear SO-239 antenna connector.

The formula for calculating amplifier efficiency percentage is:

Pout / Pin = amplifier efficiency percentage

93.7 / 170.5 = .55

or

55%!!!

As you can see you don't need to spend a lot of money on some fancy expensive lighted peak reading watt meter just to know what your 520's final amplifier's input and output RF poweris. Just use some simple math calculations and a few moments of your time, that's all you need to do.

Just some information you may not have thought about.

Jimmy,
The 520 was a working unit. It did not like the faceplate. I found a very good faceplate and was in the process of replacing it and a couple of lights. Once I got into it I found some burned wire by the transformer. It had been repaired obviously but it looked like an accident or smoke waiting to happen. I tried to replace the wires but really should have stripped the radio down further to do a good job. I also lubed the VFO and the knob and dial are not reassembled. At the end of the day the radio did not work. Something I did with the soldering of the transformer wires no doubt. The transformer itself if good. It is currently sitting with the face removed. It does have the adapter for the DG-5. I also have a non working DG-5 that I am quite sure will never work. It looked like the previous owner tried to re-flow the solder on the boards and made a mess of it.

If you want the rig with the adapter and do not make me put the face etc. back on I will let it go for $100 plus shipping.

I also have a 520-X (yes the X is correct, right on the label), think it was for overseas. It is only good for parts that much I can tell you 100%. It can go for $50 plus shipping.

I have a guy who is bidding on a very nice DG-5 that I have on EBay that wants to buy the adapter. The auction is over in a few hours and if there is any way you can respond soon it would be helpful.
Thanks
Kevin

My pal has a 830s which refuses to TX or RX on CW. My past experience with other boat anchors suggests to me that the CW filter passband requires adjusting. However I cannot for the life of me find such a trimmer beside the filters. I believe that the CW uses the SSB filter. Can anyone suggest where the trimmer, (if there really is one!) might be please?
Peace and love to all

Jon,

The TS-830 does not have any filter bandpass trimmers that some other boat anchor may have. I do NOT recommend you compare a TS-830 with some other boat anchor transceiver. Even though the 830 is a SSB and CW transceiver, it is NOT the same as other boat anchor transceivers.

Have you physically checked to see if a CW filters is/are actually installed? If the CW filter is missing then most likely the previous owner sold the CW filter separately and didn't revert the filter wiring back to the no CW filter installed connections (see page 24 in the 830 operator's manual). If the CW filter is missing simply reverse the wiring changes shown in the manual and the 830 should operate in CW mode without the filter.

Many thanks Mike. Thats very useful information. I'll pass it onto the owner. I'm sure the filter is fitted to his set. I have the same problem (almost) in that the narrow CW on one of my 830s (I have 2) has gradually stopped receiving. Last week, the signal was very soft indeed, now there is none. When I had that problem with my old FTdx401 ...(many years ago) it used to be the crsytal lattice trimmer needed tweaking but as you say, the kenwoods don't have that.
Againb many thanks

Have you checked/verified the presence of the filter select diode
switching voltage on the IF Unit when the desired filter(s) have been
selected by the Mode switch?

Loss of the filter select diode voltage will result in loss of signal
path through the filters. If both SSB and CW filter select diode voltage
is missing on the IF Unit board's SSB or CW terminals then none of the
SSB and CW filters will be selected. The transmit and receive signals
both flow through the filter's input and output diodes and if the diode
select voltage is missing then there will be no signals, either transmit
or receive, flowing through the filters resulting in the 830 appearing
to be dead.

Bryan,

The latter part of my post may not be clear: meter select switch to Ip....key rig...falling Ip...(plate current) usually indicates failing finals.

Subject: Re: [TS-520_820_530_830] Re: TS-520S Cathode and Screen Resistors

Bryan,

I know a couple of guys will beat me for this...but.....if you have, or are going to have, the replacement parts for the ones you suspect
may be faulty...replace them.

Inspect around the 12by7a driver tube socket...and the final tubes...for poor or "dry" looking solder joints. With magnification and bright light helps.

The 750VDC is too low. Measure the output of each HV cap...with a DMM/VTVM ...be careful there's lot's of HV there that will SK you. Compare the "resting/receiving" HV with the HV you get at full power and key down...should be usually no more that 10-12% drop...or as some say "sag."

Another check or two, is to tune up for full power(into dummyload), ..meter select switch to "RF" ...key rig...falling output usually indicates failing driver.

meter select switch to "Ip"...key rig.....usually indicates failing finals.

These are just some basic tests...but..helps narrow things down.
Does the fluctuation of the Ip happen on all bands or just one or two?

Subject: [TS-520_820_530_830] Re: TS-520S Cathode and Screen Resistors

Joe,

Thank you for the reply, I will check R-5 and R-6 on the Rectifier board the next time I crack the case open. The 4 resistors on the final board were definitely blown (physically cracked and out of spec on the meter) so they were replaced.

One thing that I forgot to mention (and part of what led me down the path of C-7,C-8,L-1) was that while tuning IP current fluctuates, once tuned it will start around 225 mA when I flip the send switch and then drop, over the matter of a couple seconds to 150 mA. Some information I had found online suggested that these may be the issue (especially if it is known that the resistors popped). Output power also fluctuates with the plate current.

I did replace the tubes (all 3) with what were supposed to be a "known good" set, but I have no way of truly confirming that, is there any way to confirm short of finding someone else local with a hybrid and talking them into giving the tubes a spin in their rig?

And I definitely stayed within factory spec for the resistors, I was aware that they are essentially sized to be fuses of a sort.

I will look into doing the alignment/neutralization procedure, I do know that the prior owner did not make those adjustments (prior owner is my grandfather).

On the HV reading, I am currently (after tune-up) getting 750 Volts on the meter when set to HV. Is this far enough off to suspect the HV caps?

Thank you again for taking the time to respond.

Thank you and 73s
Bryan

>
> I have a TS-520S that is not putting out what it is supposed to (only getting about 40 watts out). After a bit of digging found that the final cathode and screen resistors were cracked/blown. I bought one of the resister kits from one of the hybrid repair guys for the common final resistors that get burned out when someone goofs up (prior owner ran full power with bad coax... couldn't figure out why he kept popping fuses until he found the bad coax). So I now have 2 questions....
>
> 1. I was able to easily replace the 10 ohm and 100 ohm cathode and screen resistors. The resistor kit I got also comes with a 470 ohm 1W 5% resistor. After looking over the final as well as the schematics, I am not sure where this is supposed to go. Can anyone shed some light on where this resister is intended to go?
>
> 2. After replacing the 10 and 100 ohm resistors (and a proper tune) I am still only getting 40-50 watts into a 50 ohm dummy load. After further review I am finding mention that if the resistors are blown that it may be necessary to replace C7, C8, and L1 in the final as well, so I have ordered a kit with these 3 parts from the same vendor. So the question is is this the best next course of action? Anything else I should be replacing? (already have a fresh set of tubes in) If this doesn't work what is the next step? full re-cap? or?

Drummer4hire, pse to id with call.

You will need to inspect closely the crystals that I think are on the "OSC" board. It's been a bit since I had a 520 open. With the rig upside down....the "OSC" or HET(hetrodyne) board should be the most forward and have 7 or so crystals attached to it. Compare the crystal(s) for the band in question to what is listed in the service manual.....I think it's X-7 frequency is 37.995Mhz. More than likely a different crystal is there...with a value about 1.0 to 1.5 Mhz lower.
If this is the case...you will have to get a replacement...International Crystals...is a good place to look...or just live with it.

I gotta hand it to you...I don't want to lug around a 520...my 820 and 830 are bad enough..hihi

Also, I think that I have a picture or two in the files section dealing with this subject. I'll go and try to find them and let you know.

Hi Gang,

I read up on the why the VFo might have some dead spots, so i went in and opened the hatch and sprayed some Diox on the plates of the cap. After a few choice words i got the plate back on the VFO cover and fired it up. The Dead spot problem was gone. it worked like a charm. i did noticed that i was now drifting a bit..and its never drifted on me before. and on air check confirmed that. AND that i was off Freq by about 25KC. I went on the WWV to try and calibrate it. I thought i was suppose to adjust TC1 on the marker board. but that doesnt seem to help me much.. Is there another TC1? There is a trimmer in the can of the VFO is that the one I want? How do i put the trimmer TC1 on the marker board back to rights?

Thanks Guys

Drummer4hire, pse to id with call.

  You will need to inspect closely the crystals that I think are on the "OSC" board. It's been a bit since I had a 520 open. With the rig upside down....the "OSC" or HET(hetrodyne) board should be the most forward and have 7 or so crystals attached to it. Compare the crystal(s) for the band in question to what is listed in the service manual.....I think it's X-7 frequency is 37.995Mhz. More than likely a different crystal is there...with a value about 1.0 to 1.5 Mhz lower.
  If this is the case...you will have to get a replacement...International Crystals...is a good place to look...or just live with it.

   I gotta hand it to you...I don't want to lug around a 520...my 820 and 830 are bad enough..hihi

   Also, I think that I have a picture or two in the files section dealing with this subject. I'll go and try to find them and let you know.

I picked up another TS 520 on Ebay a few weeks ago and got it tuned up and working because it was not transmitting when I got it .....Someone has the 28.000 set to do 11 meters and all other bands are ok .....does anyone know where to start to put this thing back on track? I would like to get it back on ten meters if possible Because I would like to have it for a second radio for field days and special events.(the 28:500 and 28:900 are working fine)

Youwill need to replace the 11 meter modification crystal with the correct frequency 10 meter crystal. If you do not have the service manual for yourtransceiver, get it. You can download the operatorand service manual for your model of 520 at the following website:

www.n6wk.com/kenwood/

Do not attempt to service your model TS-520 without it. By the way, when you refer to your 520, make sure you use the correct model. There are 3 different models of TS-520. Look at the model label directly below the VFO, that's the correct model 520 you have. Download the correct operator and service manual at the above link that matches YOUR 520 model.

If the only modification that was done to put your 520 on 11 meters was to swap out the original ham band 28.0Mhz crystalthen you can purchase a new crystal, the 28.0Mhz crystal frequency is 36.895Mhz, from International Crystals in Oklahoma City, OK. Their website link is listed below.

http://www.icmfg.com/hamradio-manufacturers.html

They have an 800 number, toll free, you can call. The crystal price should be $23 plus shipping, either USPS or UPS. USPS is cheaper. Call their 800 number, select sales, then select sales representative Sara Gore, she will help you with your crystal purchase. They take all major credit cards. The typical wait time for the crystal can range from 1 to 2 weeks, that's normal. Don't think you'll get a new crystal from someone else any quicker and cheaper, they all have the same prices. I donot recommend you purchase a "used" crystal from eBay or a parts radio, you don't have a warranty and the used crystal could easily be off frequency due to age. I highly recommend International Crystals, I purchase ALL of my crystals from them and have never had a bad crystals yet and the accuracy and longevity of their crystals is excellent.

You should thoroughly check your 520 for any other modificationsand if any are found, remove the modifications so the circuit is back to its original design, BEFORE installing the new crystaland testing the transceiver for proper operation!

Did you use generous amounts of compressed air or canned air after cleaning the VFO to completely remove any/all cleaner residue BEFORE you buttoned up the VFO? If you didn't then your problem is caused by the cleaner residue you didn't remove before you buttoned up the VFO. You need to remove ALL of the cleaner residue. Also you do not spray the plates of the VFO, you apply a small amount of cleaner to the rear of the VFO's variable capacitorshaft where the shaft to frame is located then rotate the VFO knob throughout it's travel several times. You then use generous amounts of compressed air or canned air to remove any/all cleaner residue, let the VFO sit for 3 to 5 minutes then test the VFO.

thanks mike,
no, i did not use compressed air. now that it has sat overnight, will it dissipate? or do i need to go back in and used compressed air? does compressed air remove residue?
i thought i was following k4eaa's directions pretty close.
I think the dial being off by 25k might be because i over cranked when i was working the plares back and forth. thinking i was in the middle when, i was really at one end. while looking in the radio.

The cleaner most likely has evaporated over night but I don't wait that long, I remove any/all cleaner residue using forced air (canned air available at Walmart).

Anytime you use contact cleaner you should follow the cleaning process with forced air whether from an air compressor or from canned air to remove any/all cleaner residue. Never use more than is necessary to perform the cleaning of any electrical connection. Read the warnings on the cleaner's can BEFORE you use it. Most cleaning requires only a small amount of cleaner. I never recommend nor have used WD-40 as a cleaning agent. For pots I recommend DeoXit F5 fader lub cleaner and lubricant and still only use small amounts. I have used DoXit D5 on frozen "mechanical" mechanisms such as band switch bearings. I then apply a small amount of sewing machine oil to the bearing for lubrication. Frozen pots can "some times" be fixed using D5 applied at the pot's shaft point where it enters the front of the pot and allowed to "soak" into the bearing race for a few minutes. The shaft is then rotated until the shaft rotates freely. I then use forced air (canned air) to remove the residue then apply F5 Fader cleaner and lubricant to the pot. This doesn't always work especially if the pot's resistive element has been physically damaged.

The initial problem you have experienced in the VFO is instability that's caused by a very dirty variable capacitor shaft to frame DC connection at the rear of the variable capacitor. This requires applying small amounts of contact cleaner at this point then rotating the capacitor throughout its range several times. Depending on how dirty this DC connection is you may need to repeat the cleaning process more than once. Applying contact cleaner to the "plates" is not following K4EAA's instructions I'm sorry to say.

41648. Broken TS 830S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-11 18:23:15 UTC

Hi

I just bought a TS830S and had it shipped by courrier. I guess something has 'happened' during shipping as on arrival, it came on for a second or so and then blew the fuse in the radio.

Not having a 5amp, I briefly replaced with a 10amp and it came on, didn't blow but there is something not right, I immediately switched off and will be getting some 5 amp fuses tomorrow.

Any obvious areas I should be checking over to 'fix' the problem?

I know for a fact the rig was working before it was sent as it was sent by a friend and he used it to talk to me only a couple of days ago.

thanks

Garry K5XGB/G0IHB/F5VDM

I guess I took ken"s info to heart: "A health dose of contact cleaner, working the cap between its extremes several times, followed by a quality lube applied to the contacts will prepare this important cap for the next 25-35 years."

The unit has sat overnight already. I will power up tonight and see if its still drifts. If so, Blow it out. But I dont know if blowing it out at this point would help.

If steady, how do i get the the 25 KC marker back to rights, is it a matter of just lining up the dails to a 25 incriment,say at 0 and 0 and then adjusting the TCI until the tone 0 beats.

Then how to get the VFO back on freq? Is it possible that it drifted that far out and will come back once the residue problem is resolved, or is it more of a matter of adjustment?

The main problem with this rig is has been trouble free for 30 years and wasnt much need to touch it. :)

Thanks again

Steve

Steve,

I agree with Mike. The "cleaner" may have dissipated but, the junk you were trying to clean off/out probably did not.

Unfortunately...I suggest that you do it again.....do NOT button up the "side door" on the VFO...until you are certain that
all is well.

DeOxit products can be found at some electronics houses...and even music stores...especially ones that deal with
electric guitars and amplifiers. "canned air" you can find that "walmart"....I buy at costco....I go through a lot...just like
beer...I buy in 6 pack...or more...hihi

The cleaner most likely has evaporated over night but I don't wait that long, I remove any/all cleaner residue using forced air (canned air available at Walmart).

Anytime you use contact cleaner you should follow the cleaning process with forced air whether from an air compressor or from canned air to remove any/all cleaner residue. Never use more than is necessary to perform the cleaning of any electrical connection. Read the warnings on the cleaner's can BEFORE you use it. Most cleaning requires only a small amount of cleaner. I never recommend nor have used WD-40 as a cleaning agent. For pots I recommend DeoXit F5 faderlub cleaner and lubricant and still only use small amounts. I have used DoXit D5 on frozen "mechanical" mechanisms such as band switch bearings. I then apply a small amount of sewing machine oil to the bearing for lubrication. Frozen pots can "some times" be fixed using D5 applied at the pot's shaft point where it enters the front of the pot and allowed to "soak" into the bearing race for a few minutes. The shaft is then rotated until the shaft rotates freely. I then use forced air (canned air) to remove the residue then apply F5 Fader cleaner and lubricant to the pot. This doesn't always work especially if the pot's resistive element has been physically damaged.

The initial problem you have experienced in the VFO is instability
that's caused by a very dirty variable capacitor shaft to frame DC
connection at the rear of the variable capacitor. This requires applying
small amounts of contact cleaner at this point then rotating the
capacitor throughout its range several times. Depending on how dirty
this DC connection is you may need to repeat the cleaning process more
than once. Applying contact cleaner to the "plates" is not following
K4EAA's instructions I'm sorry to say.

Hi Garry,

My first guess would be that something was jarred during transport, causing a short. I'd carefully disassemble and inspect.

Hi

I just bought a TS830S and had it shipped by courrier. I guess something has 'happened' during shipping as on arrival, it came on for a second or so and then blew the fuse in the radio.

Not having a 5amp, I briefly replaced with a 10amp and it came on, didn't blow but there is something not right, I immediately switched off and will be getting some 5 amp fuses tomorrow.

Any obvious areas I should be checking over to 'fix' the problem?

I know for a fact the rig was working before it was sent as it was sent by a friend and he used it to talk to me only a couple of days ago.

thanks

Garry K5XGB/G0IHB/F5VDM

To extend the deoxit discussion a bit......

What product (number) is advised for use on a rather stiff dial? I really don't like spraying anything down with a can other than old carbs (joke)

TheVFO I recently acquired is tight. I haven't remove the dial yet (nee a fine screwdriver) but it looks like there is a friction ring inside that might be dried out? The gears are very very clean and no oxides on the case at all.

My enthusiasm for resurrecting this one cease temporarily when the connecting cable went faulty. It was very rigid and not flexible at all. Working it resulted in a separation of the small coaxial wire. I doubt I want to keep fixing it so I may redo the cable entirely for something more flexy....

Archie,

  Inside there are 3 ball bearings. The outside has the knurles...you can loosen or tighten it...to obtain the proper friction. I use a
non-petroleum based(synthetic) light weight lube...I apply it with a small bottle which has a long, small diameter tube. You can find them at hobby stores.
A few drops on the shaft that goes through the knurled
knob...rotate....rotate...rotate...will help a LOT!
  This part is packed with old grease....and sometimes just a bit of "fresh" will help.

I sent an response earlier that was incomplete so disregard it. I clicked on the SEND icon instead of cancel.

If the VFO is off frequency the same amount on all bands then I do not suspect, at this point, the VFO alignment adjustment is the source of your problem. I suspect the dial's "mechanical" alignment may very well be the source of your problem. Did you take the time to check the VFO's output frequency range using a frequency counter before you started tweaking and turning alignment components? I would not touch any electrical alignment pots, trimmers, etc, until you are absolutely sure the VFO is in fact off frequency.

41656. TS-520 for parts

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-11 22:32:08 UTC
From: Stephen - AE2S
Topic: 41656 Message: 41656

Hi all,
I have a bunch of TS-520 parts listed on QRZ if anyone is looking for spare parts.

http://forums.qrz.com/showthread.php?386995-TS-520

Regards,
Steve - AE2S

41657. Re: 520S VFO

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

i suspect its also mechanical. i think was too enthusiastic when doing a complete sweep. on WWV. I am picking up the station below the 15.000 mark. the trimer i touched was on the marker board. so i need to get that back and then deal with the mechanics. any help would be great. i dont have a freq counter.

Topic: 41659 Message: 41659

Hi. I plug in my ts830 and the transformer is smoking upon switch on. Is this fixable or is it time for a replacement? If I need to replace, anyone have a source at reasonable cost?

Thanks.

G

Won't be selling on line so I thought this would be ok to ask. What would you price a good condition Ts-520 at for sale? $250 range?

I would say anywhere between $175 and $250 is what I've seen them going for.

You still haven't stated which model of 520 you have. Look directly below the VFO knob on the front panel and you will see a thick label identifying which 520 model you have. The model label will indicate one of the following:

TS-520
TS-520S
TS-520SE

You will need to have the correct service manual for the model of 520 you have.

As I have stated, if you do not have the correct service manual for the 520 you have then you should download it, free, at the following website:

www.n6wk.com/kenwood/

and use it when servicing your 520's dial calibration issue.

First tune in WWV and adjust the VFO for a zero beat. You may have to adjust the PRESELECTOR for a peak signal. A zero beat is when you tune WWV or any steady carrier signal, until the beat note tone becomes so low in frequency that you can't hear it in the speaker. At that point the signal is considered at "zero beat". When zero beat is achieved with WWV and without touching the VFO tuning, turn the Marker ON and adjust the Marker's TC1 so the Marker signal is also at zero beat. Once the Marker signal is at zero beat stop adjusting the Marker's TC1. From now on you will use the Marker as the signal source for setting the VFO for a zero beat and the sub dial's zero at 12 o'clock. It's best at this point to disconnect the antenna so no other signal(s) interferes with the Marker signal.

The sub dial is more than likely out of physical alignment. You will have to remove the VFO knob, the Khz dial plate, the shaft bearing, the felt washer, then physically adjust the sub dial so the sub dial's "zero" is at 12 o'clock while maintaining the Marker at zero beat. The transceiver must be powered up when performing this mechanical adjustment. Once the sub dial's zero is at 12 o'clock and the Marker is still at zero beat and without moving the VFO tuning shaft, reinstall the felt washer, the shaft bearing, the Khz dial plate, and the VFO knob. Test the dial to ensure it rotates properly and the Marker is at zero beat at each 25Khz sub dial label starting at zero sub dial setting. Remember, the VFO and dial are "analog" and they more than likely will NOT be exactly on every 25Khz dial mark but they should be quite close, providing the VFO trimmers have not be messed with by you. As I said before, you should never touch any of the VFO trimmer adjustments until you absolutely sure the VFO needs adjusting. Too many

hams mistakenly jump to conclusion, the ole "knee jerk reaction",
adjusting controls that quite often do not need adjusting.

41664. TS 830S transformer

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-11 23:35:44 UTC
From: Garry W
Topic: 41664 Message: 41664

Looks like my transformer is smoking. Should I assume the transformer has had it or is there something else to check. If it's had it, can these things get rebuilt or can spares still be found.

thanks

Garry K5XGB / G0IHB / F5VDM

And of course, depending upon if there filters installed (ssb or cw) and exterior condition. W9MVM

BEST 73 and GODS BLESSINGS, MIKE & Princess Ruth.

Hi Steve. I could use the CW filter from your 520. Mine is without one and I've wanted to try code. Let me know if it's still available.
Thanks & 73,

Hi all,
I have a bunch of TS-520 parts listed on QRZ if anyone is looking for spare parts.

http://forums.qrz.com/showthread.php?386995-TS-520

Regards,
Steve - AE2S

I would disconnect the secondary and see if you can isolate to problem to the transformer or a short in the secondary side circuitry.

Put a Transformer saver in line before you go any further.
It tells how to build one in the Files section.
Disconnecting the secondaries and then reconnecting and testing them one at a time is good advice to locate the problem.

Of course it's fixable providing the transformer is not shorted out now. Do you have a call? What are your abilities to do such work? Have you got a schematic to isolate the problem? It seems to me if it is the primary smoking, it would blow a fuse. The secondary, well there are other components that would blow before smoking the transformer. The thing is that transformer is not going to smoke till a winding gets hot. I believe you should isolate the issue then find out why the fuse did not blow. Maybe check a little harder to find what is REALLY smoking in there. Transformer is not going to smoke when you plug it in. The load will blow a fuse first. Look deeper, maybe It's a capacitor or a power resistor (bleeder) that is smoking. Brad KB2CHY

Subject: [TS-520_820_530_830] Transformer smoking

Hi. I plug in my ts830 and the transformer is smoking upon switch on. Is this fixable or is it time for a replacement? If I need to replace, anyone have a source at reasonable cost?

Thanks.

Sorry, Its the 520S

I just took a listen, and its still drifting. i listen for a bit on 20 meters.

I am thinking there maybe some dislodged gunk, or residue in the VFO. i will blow it out first to see if it can stabilize, then go in for the adjustment you wrote out for me. i will see if i have a service manual in this computer, if not i will re down load.

THANK YOU for the help

steve

If you end up needing the power transformer then I have them for the 830S...
Clean & functional with no funny smells...
Sell them for $50.00 plus $12.00 to mail...
Be sure to check the circuits as best as you can...
Bob

UPDATE:
I re-cleaned and Blew out the VFO. Seems like the drifting stopped. i went on WWV and found i wasnt too far off the mark for some reason. So maybe the problem wasnt mechanical..maybe just left over gunk(?). I zero beated the marker, but when the band switch was on WWV I was not getting the tone every 25 KC..it was something around 30 some. I went on 20m to pick up the maritime net at 14.300 and i was real close on the dial. i was able to just adjust the outer plate. I turned the marker on and it was on every 25KC now. QSOed with a fellow in CA and got a freq check and i was about a 1/2 KC off.
I am wondering if have extra residue on the band switch (sprayed it the night before) good be part of the problem. and working a few times more cleaned it up.

Thanks guys

steve

Garry,

Look and see if you can see anything going on and where smole is gcoming from, there iwll be signs for sure. If you do need a new transformer, try Bob KE5FTF, pretty good on price last time I saw him seeing one.

Subject: [TS-520_820_530_830] TS 830S transformer

Looks like my transformer is smoking. Should I assume the transformer has had it or is there something else to check. If it's had it, can these things get rebuilt or can spares still be found.

thanks

Garry K5XGB / G0IHB / F5VDM

While working on my ts 520 tonight I hooked up some wires from the mode switch to the terminals they go to and when I turned the rig on it blew the fuse. I replaced the fuse and now all I get is a tone out of the speaker and the s-meter is about 3/4's of the way up.

What did I do???????

Thanks and 73's

Steve,

To verify the VFO is operating on the correct frequency range you will need a frequency counter. If you can borrow one from a friend then connect the frequency counter to the "VFO" terminal on the IF Unit board. Tune the VFO to zero on the dial, the frequency counter should display "very close" to 5.500Mhz. Tune the VFO to 500 on the dial and the frequency counter should display "very close" to 4.999Mhz.

Don't stop after only checking 2 bands, 20 meters and JJY/WWV. You should also have checked all the other bands, 160, 80, 40, 15, and 10 meters, to ensure they too zero beat the Marker signal every 25Khz. If all the other ham bands zero beat the Marker signal ever 25Khz then it would appear the VFO is, in fact, operating over the proper 5.500Mhz to 4.999Mhz frequency range and you should NOT touch any internal frequency adjustments in the VFO!!!

You said that JJY/WWV and the Marker signal zero beat about every "30Khz". If that is in fact true then that indicates the JJY/WWV HET Oscillator 23.895Mhz crystal may be off frequency by 5Khz. You can purchase a replacement JJY/WWV HET Oscillator crystal, 23.895Mhz, at International Crystals in Oklahoma City, OK (see link below) for $23 plus USPS shipping.

http://www.icmfg.com/hamradio.html

They have an 800, toll free, number you can call. They take all major credit cards.

i will see if i can find a freq counter at work. I think. oscope might do the job too. I wanted to also double check the freq on the on the marker board. the service manual says to clip on the MO...what is MO.
thanks for the tip with going through all the bands. And what freqs to look for.

steve

"MO" stands for "Marker Output"

Have you checked all the other bands, 160, 80, 40, 15, and 10 meters, to see how they zero beat with the Marker Unit signal at 25Khz dial intervals?

What test have you performed that clearly indicates the transformer is,
in fact, overheating/smoking?

Have you checked the Rectifier Unit to see if a resistor is smoking, not
the power transformer?

You have said nothing about the fuse, did it blow? Have you checked the
fuse to ensure it is the correct rating?

You need to perform further test before you are absolutely sure the
power transformer is in fact overheating/smoking.

Mike

Flea market prices tend to be lower. Last year, I picked up a TS-520S in great condition for $160 at one of these events http://www.electronicsfleamarket.com/ The receiver is better than my TS-520. WWV is +30 dB over here most days.

Topic: 41132 Message: 41681

Just thought I'd give an update on this issue. Replacing the diode on the FIX-AVR board did not solve the problem.

I am still working with another ham to try and resolve this. There is indeed a voltage drop when this happens. The 9v lines measure 6.10v when it happens, and 8.92v when it's working properly. The 3.3v line on the FIX-AVR board also drops from 3.28 to 2.26 when this is happening.

I'm going to spend more time on the AF board looking for bad connections or anything out of the ordinary, since it was the culprit of the CW sidetone issue.

If you have any other ideas for me to try, or need any more info on the issue, please let me know! I appreciate any help!

41682. Re: ts520se sidetone question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-12 23:39:48 UTC
From: tfrugia81
Topic: 41132 Message: 41682

One question, is it worth adjusting the AVR to be closer to 9v? I know the difference is minimal, but I thought I would ask. The service manual (page 10, sec 3-11) shows how to adjust it for 9v +/- 0.2v. I'm curious if 8.92 (what I'm reading under normal/working conditions) vs 8.98 to 9.02v might be enough for concern.

73

Hi Group,

I purchased a TS-530s and have not received yet. I notice in the photos
that the back of the rig has two added switches. I was wondering if anyone has any idea
what they may be for? I provide a photo in the groups photo section under my callsigns
KD6FSK. The person that I purchased the rig from has no idea. I would appreciate any help.

are the slugs in the coils still good? I know one of my 10 meter coils is cracked.

the scope i wanted was not available this weekend, i do have a line on a freq counter also..just not going to happen this weekend. I did get a fluke 45 to measure the 25KC on the marker board, but it is not picking up the signal. I do have 9 volts through. looking at the other bands the marker seems a bit off by a few KCs. when I get the right equipment, Ill make some checks

Rob,

I took a look....they could be just about anything. Need to see the inside....and be able to see where the wires go.

The two most common I've seen with this switch set up are: FREE BANDING...aka CB HACK. It alters the PLL signal path
to get above, in, and, below the CB band.

The second, is an aftermarket modification to switch filters in/out.

Tyler, the actual value of the 9V is probably not so critical that touching it up would benefit you and I certainly would not recommend it if the rig was operating normally.

However, if that adjustment VR1 is intermittent, then it will affect both the 9V and the 3.3V levels. Try this: with the power off, mark the physical setting of the trimmer VR1 as closely as you can, then turn it limit to limit several times. Reset it to the marked position, then turn on the power and set the VR1 for 9V measured from Terminal 9 to chassis. If it continues to act up, we will look into it further.

Subject: [TS-520_820_530_830] Re: ts520se sidetone question

One question, is it worth adjusting the AVR to be closer to 9v? I know the difference is minimal, but I thought I would ask. The service manual (page 10, sec 3-11) shows how to adjust it for 9v +/- 0.2v. I'm curious if 8.92 (what I'm reading under normal/working conditions) vs 8.98 to 9.02v might be enough for concern.

can you feel the transformer ,after you unplug the unit? is it hot? transformers hold heat for a long time. if not, i would agree that its something else. is it drawing a lot of current on power up? youll need a inline power meter for checking. A bad transformer will probably draw more current than a resistor. follow your nose to a burnt part... it could be under the chassis as well.

Topic: 41690 Message: 41690

What do you use? I have a couple, bought some more the other day at the only place around here that has them.

The coils for the ant, mix, and drive have different size and shape apertures in the slugs, and of the tools I have, only the drive slugs will accept one of my tools.

Is there a specification that either describes the right tool (the business end of the thing) or describes the slugs' apertures so I can get them to mate properly?

If someone has existing tools that fit, could you provide the description, name, manufacturer, specification, or any other info that might help me locate them?

I'm thinking my coil pack needs alignment...?

TS-820s
MHz - CW Watts Output / Dummy Load
28 - 90
21 - 90
14 - 70
7 - 65
3.5 - 40
1.8 - 60

G,

Did the fuse blow prior to or when the transformer started smoking?

Have you verified the fuse is the correct 6 amp fuse and not a fuse with
a much higher current rating?

Have you visually checked the Rectifier Unit for overheated components
such as resistors as well as wiring in and around the area of the
Rectifier Unit board?

What other checks have you done that would produce results that points
to the transformer as the source of the "smoke"?

Topic: 41690 Message: 41692

I have accumulated a collection of tuning tools, including from Radio Shack (they rarely have them any more) and Fair Radio.

But the problem with the coil cores in the TS-820S is that nothing fits them very well. The plastic tools bend too easily and metal screwdrivers both affect the measurement and tend to crack the coil slugs.

So here is what you should do. Get a wooden dowel, about 3/16 in dia or thereabouts (package of various sizes available at Wal Mart for about $1.59). File down the end to a "chisel" point. Then lop off the very end of the chisel point to make it blunter and cut off the sides of the point so it is just wide enough to fit the coil slugs.

Of course, if you screw up you can just cut the end off and start over.

Once you have it right, dip the tip in polyurethane varnish or coat it with superglue and let it dry throughly.

Also, take another dowel and file it down to chisel point to use for turning the final neutralizing cap without electrocuting yourself.

The thing I have not found yet is a tuning tool that is both nonmetallic and strong enough to tune the carrier unit adjustments without affecting the frequency. I have to use a metal screwdriver and repeat the adjustments as required.

Good Luck!

Hello Paul,

There are a couple of sources for the kenwood alignment tools & other parts that members of this reflector have used with success. One is Ken Kemski who can be found at www.k4eaa.com. Not only parts but a great deal of info as well. Another is http://www.hybridrestore.com/parts/. Many will recommend Bob Mansker as well. I've also gotten a nice set of tools from The Tube depot www.tubedepot.com. I'm sure others can supply info/encouragement as well as advice on shaping/modifying your existing tools to thee job at hand. Good Luck! You're in the right place to getting your hybrid health back in order.

i have..I need to look at this closer. sometimes it appears to be off other times right on the money. so at this point I am not 100% on this question. perhaps the band switch ? I sprayed it, but failed to blow it afterwards. I will revisit that task today.
on air checks so far VFO is dead on with other hams.

Joe,

I just received a msg from person I purchased the ts-530s and he stated that switches are for the CB band. He said if there up its for CB and down is for Ham bands. Is this going to affect the rig or do I just leave it alone. He also stated that the rig is working on all bands with 100 watts output.

Rob,

  I took a look....they could be just about anything. Need to see the inside....and be able to see where the wires go.

  The two most common I've seen with this switch set up are: FREE BANDING...aka CB HACK. It alters the PLL signal path
       to get above, in, and, below the CB band.

   The second, is an aftermarket modification to switch filters in/out.

Hi Group,

I purchased a TS-530s and have not received yet. I notice in the photos
that the back of the rig has two added switches. I was wondering if anyone has any idea what they may be for? I provide a photo in the groups photo section under my callsigns KD6FSK. The person that I purchased the rig from has no idea. I would appreciate any help.

Rob,

That is very common. You can leave it be.....and mark the switches as to what they do....ie..."up" CB..."down" HAM....or remove the mods.
Depending on which way the mods were done...it could take 10 minutes to and hour or more to properly remove.

It is possible that the 10 meter coils..."ANT," "MIX," and "XMIT(or drive) coils my have been "adjusted."

Please note that: It is illegal for you to operate this rig in/on the 11meter(CB) band...or any others for that matter...outside of the band plan/restrictions/conditions of your license...except for some very rare instances spelled out in Part 97 of the FCC Rules & Regulations.

It's up to you what you choose to with it. As Stated to another member of this board..ANY rig that crosses by path or bench...will have ANY CB HACK or
FREE BANDING REMOVED..or I won't work on it.

41698. BS-8 adapter.....my radio a 520S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-13 18:47:55 UTC
From: n3kvl
Topic: 41698 Message: 41698

Hello All,

I opened the sm-220 and looked at the adapter and it a BS-8 not a BS-5. Its marked on the bottom. So I assume that it is not going to work with the TS-520S? The manual indicate a BS-5 for the 520.

Is this trading material? Anyone?

Thanks
Archie

I can't answer that question Archie. You could put a posting to see if
anyone has a BS-5 to trade for your BS-8.

Only the "pan" junction will not work probably. The rest of the SM-220, monitoring your transmit signal and monitoring receive signals will work properly. Over the years, I've found the panadapter function of the SM-220 somewhat useless but it makes for nice station eye candy. The real value of the SM-220 is monitoring your transmit signal and to a somewhat lesser extent, monitoring receive signal waveforms.

Thanks Allan. I did as you suggested, but having same symptoms.

However, I think I have a HUGE clue. While tooth picking around the AF board, the radio went deaf. Since I had the bottom open and was near it, I heard the relay RL2 CLICK and audio was restored. I noticed this twice! I've previously pulled the relay and reseated it (looks brand new), but now I believe this is the culprit. I'll look trough my previous notes to see what the next step may be.

I took the relay cover off so I could see what was happening when the radio goes deaf. I made a video of it (http://www.youtube.com/watch?v=9YHssBUzq20). The radio goes deaf at 1m 27s, and comes back at 2m 2s.

The relay doesn't seem to do anything when the radio goes 'deaf', but definitely flutters when it comes back alive. Is it still worth cleaning it out, or is this just a byproduct of the real issue?

Thanks for any help!

41705. Tune-Up procedure for TS-820S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-13 22:14:37 UTC
From: bsmply
Topic: 41705 Message: 41705

Greetings to the group. I tried to join today's 40m net on my TS-820S, but I was not heard, so I had to fail back to my Yeasu FT-897 :(. Oh well.

First, my name is Burton (I go by anything close to it). I've been a member of the group for a while, but this is my first post. I've enjoyed the group and all the help I've seen on here.

I think the reason nobody could hear me on the group net with my 820S is I'm still a rookie at the tune-up procedure when changing bands. I tried to follow the procedure listed in the files section of this group, specifically for the 820S. Here's the link - http://groups.yahoo.com/group/TS-520_820_530_830/files/OPERATOR%20AIDS (file--> operator aids --> tuneup.doc). I don't know if it's the rig or my lack of knowledge on how to use it.

Is this the correct document to be used? If so, I have some comments/questions about this procedure.

On page 1, step 1: Why is the position of the "standby switch" listed twice?

On page 2, step 5: With the meter set to "ALC", the procedure states to "peak the meter", however it's not clear if this is meant to only peak the meter within the ACL scale, or to the edge of the meter. Which peak and I shooting for?

On page 2, step 6: My meter starts at about 225ma, then when I flip the standby switch to "send", the meter drops to ~60 - 90 ma (never exceeds 100 ma), but there is no specific "dip" - ie, regardless of how I adjust the plate knob, the meter appears to drop, then stays around the same reading and does not really move until I release the standby switch.

Since I'm not sure about the settings, I've never really moved the "car" setting from the 9 o'clock position as stated in step 1. The manual defined the CAR setting as the carrier level adjustment for CW and implies that adjusting it will not affect SSB. Am I interpreting this incorrectly?

I guess I'm a little confused. Following the net, I fired up the 820 again and found the W3SGJ special event booming on 7.240.0 and tried to call out, but I made a hybird rookie mistake, I turned off the heaters while listening ... and forgot to turn them back on until it was too late. I guess I'm not the only person to make this mistake.

I have plans next weekend and will not be able to try the net then. Maybe some other time.

Also, just wondering if anyone from this group is in the greater Philadelphia area and would be willing to make a trip to my QTH to show me how to tune this rig?

Hi Burton, you can find the tuneup procedure for "kenwood HYBRID" at www.K4eaa.com/tune-up.htm I hope that this will help you. W9MVM.

BEST 73 and GODS BLESSINGS, MIKE & Princess Ruth.

Excellent suggestions above. I have taken some of the hard plastic electronic alignment tools (say from Radio Shack) and trimmed them down to fit the coil slots with a very sharp knife or a razor blade (careful!). Hope that helps.

Hello Tyler,

I recently had an issue similar to what you describe with a TS-520S. It was related to the 9V off of the FIX CH AVR UNIT. The POT VR1 had partially failed (one side of the wiper tab that holds it on had broken off partially) such that the wiper was making random/intermitted contact which was causing the 9V to randomly fail/go out of tolerance.

I am not sure if this would cause the relay to glitch when it comes back on or not.

Just another thing to look at if you did not do so already.

73,

Roger (AE3RT)

Rob,

That is very common. You can leave it be.....and mark the switches as to what they do....ie..."up" CB..."down" HAM....or remove the mods.
Depending on which way the mods were done...it could take 10 minutes to and hour or more to properly remove.

  It is possible that the 10 meter coils..."ANT," "MIX," and "XMIT(or drive) coils my have been "adjusted."

  Please note that: It is illegal for you to operate this rig in/on the 11meter(CB) band...or any others for that matter...outside of the band plan/restrictions/conditions of your license...except for some very rare instances spelled out in Part 97 of the FCC Rules & Regulations.

It's up to you what you choose to with it. As Stated to another member of this board..ANY rig that crosses by path or bench...will have ANY CB HACK or
FREE BANDING REMOVED..or I won't work on it.

Joe,

I just received a msg from person I purchased the ts-530s and he stated that switches are for the CB band. He said if there up its for CB and down is for Ham bands. Is this going to affect the rig or do I just leave it alone. He also stated that the rig is working on all bands with 100 watts output.

Rob,

I took a look....they could be just about anything. Need to see the inside....and be able to see where the wires go.

The two most common I've seen with this switch set up are: FREE BANDING...aka CB HACK. It alters the PLL signal path
to get above, in, and, below the CB band.

The second, is an aftermarket modification to switch filters in/out.

I think what you observed with the relay is an effect rather than the
cause of your problem. The two relays are not activated while in the
receive state. That is why you didn't observe any relay activity when
the receiver went deaf. They are supplied with 12V by Q8 in the VOX
unit when transmitting. When the 9V came back up to normal, a transient
probably caused Q8 to turn on briefly causing the relay action. Q8 is
normally cut off and thus doesn't supply any voltage to the relay coils.

It still appears to me that the problem is on the FIX CH AVR unit. One
other thing to check though is to verify that the 14V coming into the
FIX CH AVR unit remains at 14V at the same time that the 9V output
is acting up. If the 14V is steady then we will look closer at the 9V
problem. Roger (AE3RT) made a good suggestion on looking closely
at VR1.

I took the relay cover off so I could see what was happening when the radio
goes deaf. I made a video of it
(http://www.youtube.com/watch?v=9YHssBUzq20).
The radio goes deaf at 1m 27s, and comes back at 2m 2s.

The relay doesn't seem to do anything when the radio goes 'deaf', but
definitely flutters when it comes back alive. Is it still worth cleaning
it out, or is this just a byproduct of the real issue?

Thanks for any help!

Hi, I was recently thinking of reducing the output from either my 820 or 530 to a lower level, not quite QRP but around 10 to 25 watt level. It occurred to me that the easiest way to do this would be one of the following methods, one , move the HT tap on the transformer down to the 400v tag or ,two, remove the doubler and fit full wave IE 400-0-400 bridge rectifier. This will have some effect on the anode impedance but the tank circuit should easily be taken care of, what do you think and has anyone tried a similar thing. Moving the HT to the 400v tag is the easiest and simplicity itself to restore to original.

I solved this problem for a guy years ago, nothing wrong with the eqpt but he bought the rig used and the switch at the left end of the row was at TX, every time he plugged it in the PA was running flat out off tune, things got warm very rapidly. Not having seen the rig before he had not noticed, once the smoke started his brain went to panic mode!.

Gary did not say "when" the transformer supposedly started smoking. Did it occur when power was first applied or did it occur after the 830 was powered up for any length of time?

Gary needs to do some troubleshooting to determine if, in fact, the power transformer is smoking. It's quite possible the smoke is coming from a component on the Rectifier Unit or wiring around the power supply area that's seeping through small openings around the transformer giving the false impression the transformer is smoking.

Topic: 41712 Message: 41716

Decreasing Anode supply voltage is not the "easiest and simplest" method to reduce output power or have a load control.

Two much easier ways:

1. Use the 9vdc battery and pot to provide negative control voltage to the ALC bus line. This controls TIF Amp rf output level.

2. Add a pot to control the screen grid voltage (210A) of the 12BY7A Driver tube. Can add a fixed resistor to lower the screen grid voltage (start with approx 33k ohm) or add a pot. HeathKit used a 25k ohm pot as a Load control by varying the screen grid voltage of the 5763 Driver Tube in its DX-100. This results in having a "load control" that adjusts the level of RF output from the Driver stage to the Finals.

41717. Re: [TS-520_820_530_830] Tune-Up procedure for TS-820S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-14 11:32:56 UTC
From: Paul Nussbaum
Topic: 41705 Message: 41717

Here are my long winded thoughts about it. Maybe you will find something here that is helpful...
In addition to the TS820S user manual, and service manual, I have found a handful of tune-up procedures for this on the Internet - they are all similar and all different, and none of them seems to address specific questions like this...

1] Where to set the carrier (CAR) when peaking the DRIVE with the meter on ALC on TUN mode

Some methods indicate a starting setting for CAR at 1/2 to 3/4 up (past 12 o'clock) and say reduce it if the meter pegs the right side. Some say start it about 9 to 10 o'clock. One says says set the CAR so that the DRIVE peak is about 1/8" to 1/4" just past the "ALC box"... so it lines up about where the 250ma line is on the meter.

The user manual states that the nominal Ip for CW operation should be 200ma. I find that if I start with the CAR very low, peak the DRIVE in ALC, then bring up the CAR so that the DRIVE peak sets at the top of the ALC box, after the tuneup, I have 200ma on the meter when set to Ip. For my high bands, this is a CAR of about 9-10 o'clock with CW putting out 90-100 watts.

So, what I do is set the CAR so that the DRIVE peak on ALC is at the top of the ALC box.

2] Most of the procedures then have you dip the PLATE with the meter on Ip in TUN mode.

It is hard to see the dip using a dummy load at the reduced output power of TUN mode.

I actually skip this step and do the next step of peaking the RF output using the PLATE and LOAD in TUN mode rather than CW mode.

If you do this PLATE and LOAD walking up the RF in CW mode (after dipping the PLATE in TUN mode) as most procedures indicate, you have to do it in steps of a few seconds, switching back and forth from SEND to Receive. Doing it in TUN at reduced power, you can do the whole walk up in one SEND session.

3] Most procedures, after dipping the plate in TUN, have you switch mode to CW, set the meter to RF, and use the PLATE and LOAD alternating to walk up the peak RF. Typically, they then say you are ready to go, but when I do that, the Ip is well beyond the 225ma so many recommend as max Ip. Pulling it back down using the LOAD control is not recommended because of noise balance. Pulling it down with the CAR control tends to put you in a loop of re-peaking the RF with the PLATE and LOAD, then checking Ip and dipping the PLATE again...

4] It is never mentioned, but after setting the bias to 60ma, one will notice (when the key is plugged in) that switching to SEND shows 75ma in CW (but 60ma in either USD or LSB). CW is class C operation on these things, and the 75ma bias in CW mode is correct.

So, in summary, here is how I do it - just three steps - it is fast, I think i is safe for the tubes, and it results in what I think are the correct values for operation:

1]Meter - ACL
Mode - TUN
CAR - way down (just enough to get a meter movement)
Switch to SEND
Peak DRIVE
Bring up CAR to set the DRIVE peak at the top of the ALC box
Switch to Receive

2]
Meter - RF
Mode - TUN (not CW)
Switch to SEND
Walk up peak RF with PLATE and LOAD
Switch to Receive

3]
Meter - Ip
Mode - CW
Switch to SEND
Dip the PLATE
Switch to Receive

What I find using this method is that the plate dip ends up at about 200ma and output is 90-100W for the high bands. The whole process takes about 15 seconds. Dipping the plate last lets you verify the Ip value at the same time, and if the neutralization of your finals is very close, the last step of dipping the plate will need virtually no adjustment - the walking up of the plate and load for max RF will be right there.

This method comes from http://www.hybridrestore.com/tuning-your-hybrid/

here

The only difference being that I don't do the very last part of peaking RF out... his procedure is for repair testing, so he goes to 225ma and is looking for output from a performance / problem perspective. I like to go with 200ma for the long term.

Hope this helps.
Paul

Hi Burton, you can find the tuneup procedure for "kenwood HYBRID" at www.K4eaa.com/tune-up.htm I hope that this will help you. W9MVM.

BEST 73 and GODS BLESSINGS, MIKE & Princess Ruth.

Topic: 41705 Message: 41718

In addition to the TS820S user manual, and service manual, I have found a handful of tune-up procedures for this on the Internet - they are all similar and all different, and none of them seems to address specific questions like this...

1] Where to set the carrier (CAR) when peaking the DRIVE with the meter on ALC on TUN mode

Some methods indicate a starting setting for CAR at 1/2 to 3/4 up (past 12 o'clock) and say reduce it if the meter pegs the right side. Some say start it about 9 to 10 o'clock. One says says set the CAR so that the DRIVE peak is about 1/8" to 1/4" just past the "ALC box"... so it lines up about where the 250ma line is on the meter.

The user manual states that the nominal Ip for CW operation should be 200ma. I find that if I start with the CAR very low, peak the DRIVE in ALC, then bring up the CAR so that the DRIVE peak sets at the top of the ALC box, after the tuneup, I have 200ma on the meter when set to Ip. For my high bands, this is a CAR of about 9-10 o'clock with CW putting out 90-100 watts.

So, what I do is set the CAR so that the DRIVE peak on ALC is at the top of the ALC box.

2] Most of the procedures then have you dip the PLATE with the meter on Ip in TUN mode. It is hard to see the dip using a dummy load at the reduced output power of TUN mode.

I actually skip this step and do the next step of peaking the RF output using the PLATE and LOAD in TUN mode rather than CW mode.

If you do this PLATE and LOAD walking up the RF in CW mode (after dipping the PLATE in TUN mode) as most procedures indicate, you have to do it in steps of a few seconds, switching back and forth from SEND to Receive. Doing it in TUN at reduced power, you can do the whole walk up in one SEND session.

3] Most procedures, after dipping the plate in TUN, have you switch mode to CW, set the meter to RF, and use the PLATE and LOAD alternating to walk up the peak RF. Typically, they then say you are ready to go, but when I do that, the Ip is well beyond the 225ma so many recommend as max Ip. Pulling it back down using the LOAD control is not recommended because of noise balance. Pulling it down with the CAR control tends to put you in a loop of re-peaking the RF with the PLATE and LOAD, then checking Ip and dipping the PLATE again...

4] It is never mentioned, but after setting the bias to 60ma, one will notice (when the key is plugged in) that switching to SEND shows 75ma in CW (but 60ma in either USD or LSB). CW is class C operation on these things, and the 75ma bias in CW mode is correct.

So, in summary, here is how I do it - just three steps - it is fast, I think i is safe for the tubes, and it results in what I think are the correct values for operation:

1]
Meter - ACL
Mode - TUN
CAR - way down (just enough to get a meter movement)

Switch to SEND
Peak DRIVE
Bring up CAR to set the DRIVE peak at the top of the ALC box
Switch to Receive

2]
Meter - RF
Mode - TUN (not CW)
Switch to SEND
Walk up peak RF with PLATE and LOAD
Switch to Receive

3]
Meter - Ip
Mode - CW
Switch to SEND
Dip the PLATE
Switch to Receive

What I find using this method is that the plate dip ends up at about 200ma and output is 90-100W for the high bands. The whole process takes about 15 seconds. Dipping the plate last lets you verify the Ip value at the same time, and if the neutralization of your finals is very close, the last step of dipping the plate will need virtually no adjustment - the walking up of the plate and load for max RF will be right there.

This method comes from http://www.hybridrestore.com/tuning-your-hybrid/

The only difference being that I don't do the very last part of peaking RF out... his procedure is for repair testing, so he goes to 225ma and is looking for output from a performance / problem perspective. I like to go with 200ma for the long term.

Hope this helps...

Hi

Thanks for all the responses so far. Yes it blew the fuse when I first plugged it in, so I upped the fuse to see what would happen. It seems that the smoke is from the transformer and when I switched off, I could hear 'crackling'inside the transformer. I have now purchased a replacement and removed the original.

I did pit power back into the old one once removed from the 830S and there was sign of a problem, however without any load on the transformer. I will swap the other out ans see what happens

regards

Garry

Rob,

That is very common. You can leave it be.....and mark the switches as to what they do....ie..."up" CB..."down" HAM....or remove the mods.
Depending on which way the mods were done...it could take 10 minutes to and hour or more to properly remove.

  It is possible that the 10 meter coils..."ANT," "MIX," and "XMIT(or drive) coils my have been "adjusted."

  Please note that: It is illegal for you to operate this rig in/on the 11meter(CB) band...or any others for that matter...outside of the band plan/restrictions/conditions of your license...except for some very rare instances spelled out in Part 97 of the FCC Rules & Regulations.

It's up to you what you choose to with it. As Stated to another member of this board..ANY rig that crosses by path or bench...will have ANY CB HACK or
FREE BANDING REMOVED..or I won't work on it.

Joe,

I just received a msg from person I purchased the ts-530s and he stated that switches are for the CB band. He said if there up its for CB and down is for Ham bands. Is this going to affect the rig or do I just leave it alone. He also stated that the rig is working on all bands with 100 watts output.

Rob,

  I took a look....they could be just about anything. Need to see the inside....and be able to see where the wires go.

  The two most common I've seen with this switch set up are: FREE BANDING...aka CB HACK. It alters the PLL signal path
       to get above, in, and, below the CB band.

   The second, is an aftermarket modification to switch filters in/out.

Thanks Joe,

I will wait to get the rig in and will remove the mod.

Rob,

That is very common. You can leave it be.....and mark the switches as to what they do....ie..."up" CB..."down" HAM....or remove the mods.
Depending on which way the mods were done...it could take 10 minutes to and hour or more to properly remove.

  It is possible that the 10 meter coils..."ANT," "MIX," and "XMIT(or drive) coils my have been "adjusted."

  Please note that: It is illegal for you to operate this rig in/on the 11meter(CB) band...or any others for that matter...outside of the band plan/restrictions/conditions

of your license...except for some very rare instances spelled out in Part 97 of the FCC Rules & Regulations.

It's up to you what you choose to with it. As Stated to another member of this board..ANY rig that crosses by path or bench...will have ANY CB HACK or
FREE BANDING REMOVED..or I won't work on it.

Joe,

I just received a msg from person I purchased the ts-530s and he stated that switches are for the CB band. He said if there up its for CB and down is for Ham bands. Is this going to affect the rig or do I just leave it alone. He also stated that the rig is working on all bands with 100 watts output.

Rob,

  I took a look....they could be just about anything. Need to see the inside....and be able to see where the wires go.

  The two most common I've seen with this switch set up are: FREE BANDING...aka CB HACK. It alters the PLL signal path
       to get above, in, and, below the CB band.

   The second, is an aftermarket modification to switch filters in/out.

Hi Group,

I purchased a TS-530s and have not received yet. I notice in the photos
that the back of the rig has two added switches. I was wondering if anyone has any idea
what they may be for? I provide a photo in the groups photo section under my callsigns
KD6FSK. The person that I purchased the rig from has no idea. I would appreciate any help.

Hi Burton,

I am located in Cherry Hill, NJ and might be able to help you. I have two Kenwood hybrids, a TS-830S and TS-520S. Contact me off list if you want me to help.

73,
Tony (N2ATB)

41724. KENWOOD HYBRID USER NET (April 14th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-14 18:38:31 UTC
From: mvgilger
Topic: 41724 Message: 41724

The Saturday's net on 40 meter we had 17 stations checking with good band conditions. There were 2 new stations checking in, N9TB, KA1SJD, KC2OUC. Out of those, there was:

6 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 10 stations checking in under very poor band conditions. We had 1 new check-in, W0HR

Out of those, there was:

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 33, Sunday's total = 19 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Thanks Alan and Roger!

I check vr1 again and it appears ok to my eye. I may rotate it several times again to see if I notice anything.

I measured the three lines again (14v, 9v, and 3.3v) on the Fix-Avr board.

Here is what they read, working vs deaf:

14.29v working 14.76v deaf
8.99v working 6.16v deaf
3.31v working 2.2v deaf

I appreciate the help guys!

Hello Alan,

It seems like something is definately malfunctioning in the regulator circuit rather than a short circuit of some sort since the 14v line increases when the issue happens. I would think that this indicates a decrease in loading since the 14v is an unregulated supply.

Also, the 3.3v is derived from the 9v and changes in exact proportion to the change in the 9v. So the issue seems to be coming from the regulation circuit for the 9v in my mind.

I have had issues with some of the older transistors in the TS-820/TS-520 becoming marginal in their operation due to age. But only in oscillating circuits.

It seems interesting that the 9v seems to lock into the zener diode reference voltage when it does fail, instead of driving the output voltage of the regulator circuit to the 9v it should. I will need to think more about this circuit to think of a failure that would cause this scenario, although Q6 and its associated componants would appear to be at the center of what is happening here. It might be interesting if you have some canned air to blow it on Q6 to see if the issue goes away when this is done. You can also carefully (without spitting) blow through a straw to cool the transistor.

Otherwise, I think the next step would be to start probing different points in the feedback/regulation circuit to see which part of the regulator circuit is breaking down.

I'll give it more thought, but there is my two cents worth.

73,

Roger (AE3RT)

Hi Roger!

Thanks for the info. Very good points.

I took a closer look at Q6. It looks like it has been out of the board at some point (fresh solder on all 3 legs). It is the right part #.

While poking around the radio went deaf once and has not done it again. I'm going to let it "cool down" more and try again. I will run to town and get more air.

73, and thanks again for the help!

I agree 100% with Roger...you have a problem with the regulator since the 14V line was not loaded down when the 9V line dropped.

Take some voltage measurements on the transistors in the regulator circuit under normal and deaf conditions. Also inspect closely the solder connections on Q6 since you said it has been replaced.

Alan, KD5R

Subject: Re: [TS-520_820_530_830] Re: ts520se sidetone question

Hi Roger!

Thanks for the info. Very good points.

I took a closer look at Q6. It looks like it has been out of the board at some point (fresh solder on all 3 legs). It is the right part #.

While poking around the radio went deaf once and has not done it again. I'm going to let it "cool down" more and try again. I will run to town and get more air.

73, and thanks again for the help!

cause this scenario, although Q6 and its associated componants would appear to be at the center of what is happening here. It might be interesting if you have some canned air to blow it on Q6 to see if the issue goes away when this is done. You can also carefully (without spitting) blow through a straw to cool the transistor.

Excellent, thanks guys!

I took some measurements on Q6 and Q7. Numbers show collector, base, and emitter respectively.

Q6 normal conditions:
6.02, 5.95, 5.37

Q6 while deaf:
4.06, 4.53, 5.31

Q7 normal conditions:
6.04, 9.02, 5.40

Q7 while deaf:
5.95, 6.09, 5.30

Hi friends,

My friend 4s7ef, recently developed a problem in his 820S.According to him this is how he described the problem.

1.To-day I switched on the rig and listing on 40 meters.Every thing was ok and signals were 59+
2.Had a QSO on 40 meters with another HAM and received him at 59+
3.Suddenly his signal level dropped to 53.
4.Then switched off the AGC then the S meter needle swung to the extreme right
5.Transmission got distorted
6.Switched off 820s

Am going to get his rig to see what has gone wrong.Grateful if any one points me to probable areas to look at.

73's de 4s6rav (Ravi)

Hello Allen,

I suspect your base and collector readings are reversed because of the Japanese transistor configuration (bce not cbe as we are used to in usa
).

With that in mind it looks like vr1 still is ok when the radio goes deaf. It is 2/3 of the output voltage under both cases.

Q7 appears to still be biased on by the base emitter values shown, but Q6 appears to have become shut off during the malfunction. But since the voltage at the base of Q6 is only about 4 volts that would be expected with a emitter voltage of 5.3 volts.

This is the fun of feedback circuits:-) How did we get to this state? I suspect the real culprit is Q5 or Q4. The feedback/servo correction of the regulator circuit should not have allowed this state to occur. The reduction of output voltage should have caused Q5 to drive Q4 to regulate the current and keep the voltage at a proper level. It appears that even during the fault condition that Q5's base emitter junction should still be on allowing Q4 to be on. This would be what I would look at next.

I still don't think a short circuit on the regulated output would get us to this state, I suspect Q5 has stopped working properly to get us to this state. You might try cooling Q5 with air to see if the circuit gets out of its funk.

I hope this helps.

73,

Roger (AE3RT)

supply.
> > >
> > > Also, the 3.3v is derived from the 9v and changes in exact proportion to the change

in the 9v. So the issue seems to be coming from the regulation circuit for the 9v in my mind.

> > >
> > > It seems interesting that the 9v seems to lock into the zener diode reference voltage when it does fail, instead of driving the output voltage of the regulator circuit to the 9v it should. I will need to think more about this circuit to think of a failure that would cause this scenario, although Q6 and its associated componants would appear to be at the center of what is happening here. It might be interesting if you have some canned air to blow it on Q6 to see if the issue goes away when this is done. You can also carefully (without spitting) blow through a straw to cool the transistor.

Ravi:

It is hard to do 3rd party help as cant ask clarifying questions directly to rig operator who witnessed the problem. Here are some suggestions based on my interpretation of what you have posted:

1. Remove Aux Relay from Relay Unit Board and clean contacts with copy paper wetted with contact cleaner while applying gentle pressure to the armature.

2. When switching AGC to Off position it is not uncommon for audio to be distorted on strong signals so you need to ride the RF gain control. However, S-meter should not peg with AGC in off position unless he ran RF gain pot full CCW. Anytime S meter pegs with no signal you have very low voltage on the AGC bus line (rail). The lower the voltage the higher the S-meter will indicate. May be a couple of things going on here. It sounds like may have lost -6vdc. -6vdc is used to back bias the AGC detector diodes to establish agc threshold. -6vdc is also applied to base of AGC detector amp Q16 when you place AGC switch in OFF position to keep transistor biased off so no affect on agc bus line with strong signals detected by the AGC diodes.

3. Suggest you read couple of dc voltages at IF board. At Conn IF-3 Pin 7. Should be approx -5.9vdc with AGC switch in Off position and approx -5.6 vdc with AGC in Fast or Slow position. Also, suggest you measure AGL at Pin 6. Should be 3.3 vdc. Problem is most hams do not have a high Z meter for AGC bus line (rail) measurement. Using a 11 meg ohm VTVM you will likely pull Pin 6 down to approx 2.7 vdc. Cheap DMM even worse. Much less than 2.7vdc and I would check RF-1 at AVR board. Dont need high Z meter to measure RF-1.

A suggested approach:

If you want to get your rig back on the air buy a replacement AVR board from Bob Mansker. Easy to dummy load test the 9vdc regulated and 3.3 RF-1 on your bench before you install the replacement board.

Then you can spend your free time troubleshooting the old board out of the rig where you will have ready access to get CBE readings from the foil side of the board. You already know someone before you has worked on the board and you replaced the reference zener based on someones good intentions. There are couple of folks here who appear to understand transistor testing and linear regulators. Make it easy on yourself by gaining ready access to foil side of board and learn in the process.

This is a pretty old and simple series pass regulator. Once you can easily access the transistor leads you can take CBE readings and can test transistors by doing forward bias turn on and turn off testing.

I can help you with dummy load sizing for bench testing.

Ordinarily I would not recommend replacing active devices that have not failed but Q4 pass transistor runs pretty hot in this regulator. If you take board out you may want to consider replacing it. I think there are couple of fellows on here who have supply of original devices.

Just a suggestion to get you back on air quickly. If in no rush to get rig back on the air proceed as you are. Just be very careful not to drop any solder or wire clippings into rig when repairing board in place.

I will let the fellows helping you proceed with how to troubleshoot this circuit.

41735. TS 520 Final Amp wafer band switch arcing

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-16 00:23:20 UTC
From: Dadatcomputer
Topic: 41735 Message: 41735

I have a TS 520 that when I transmit on SSB arcing occurs on the band switch wafer under the Final amp compartment. Has anyone else had this happen and is there any replacement parts available to replace the arced wafer. Wonder if cleaning and corona dope would help.

41736. Re: [TS-520_820_530_830] Re: ts520se sidetone question

Hi Guys,

Thanks for the email Terry. You may be right. I'm not in a huge rush to get the radio fixed, and I'd definitely rather spend $4-5 on parts than $50+ on a new board if possible. If that's what is needed I'm happy to do it though (I understand my lack of experience with electronics is another factor here). I am enjoying the experience though, and learning a lot looking through the schematics and with the help of Alan, Roger, and others. I appreciate all of the help, and if a new board is the best solution, that sounds good to me (this IS my first rodeo with this type of repair :)).

I took measurements on the 3 legs of Q4 and Q5. You were right, Roger, I was wrong on my CBE.

Q5 reads the following, in BCE:

Good: 5.94, 13.5, 5.33
Bad : 4.64, 4.6, 3.96

Since Q4 is circular, I wasn't sure how to read it. I will refer back to the schematics to determine which is BCE, and will update this, but the readings were:

Good: 9.00, 14.34, 13.65
Bad : 6.18, 14.75, 3.96

One more thing. Q4 DOES get hot while the radio is deaf. Q5 gets warm, but not too hot. However, the large blue resistor on the top right of the board gets too hot to touch (here is a picture of it: http://screencast.com/t/CiEUSXSh4a2). I blew on that resistor while it was 'deaf' and it came back to working pretty quick, although that may have just been a coincidence.

If this helps please let me know. If a new board is the best solution, please let me know as well, but I'm willing to do/try whatever is best!

73,

-Tyler

I have the complete band switch for the 520...
Sell them for $22.00 plus $3.00 to mail...
You might try cleaning with DeoxiTT first though...

Hello Tyler,

Q5's BE junction looks to be on, but Q4's is definitely not on!

Q5 appears to have collector current flowing and CE voltage drop of 0.64 which appears to indicate it is operational in the fault condition.

Q4, however, is definitely off and would appear to be your problem. There is no reason Q4 should not be active and the readings indicate that it is not.

Have you tried to cool Q4 when the fault occurs?

If you would like, you could get a new board, but at this point everything seems to point at Q4 as the failing component.

Hope this helps.

Hello Tyler,

Also, if I am looking at the correct resistor (R21) appears to be part of the -6v circuit not the 9v circuit. However, the board you have is very different from the board in my 520s...

Looking at the 520se service manual shows that this -6 is generated off of the -C dc ("100"v DC) off the rectifier board in the 520se. There is quite a voltage drop and just a basic power calculation would seem to indicate that this resistor would normally run pretty hot! This would seem to be normal.

Excellent, thanks Roger. I don't see R21 on the schematic, but that's what it shows on the board.

I will replace Q4. NTE129 appears to be the replacement. Does the (l) at the end of 2SA606 (l) designate a different model, or will the standard NTE129 work ok? I will pick up several.

There is quite a voltage drop and just a basic power calculation would seem to indicate that this resistor would normally run pretty hot! This would seem to be normal.

I had a dead side tone. You don't have to spend $50 on a board. i purchased mine off ebay for $15 to the door. I really wanted to repair on a component level but for that price, it was hard to justify. Switched the board out and it works great. I narrowed it down to a transistor. I'm gong to remove it to take readings and hopefully fix the board and have a back up!

Hi to all,
the time constant of the AGC of my TS-830S (slow position) is, in my opinion, too fast and I would like to change the value of C177 in the IF unit.
I would like to know if anyone has done this change and what is the value used to replace C177.

All the recent postings on smoking transformers and such has caught my attention. I looked at the drawings for the TS830 and really don't see any inrush current limitation on AC for the power supply and also the filiment circuit for the finals. With these old eyes, maybe I missed something.

Has anyone installed any devices such as thermisters for inrush current? If so,and keeping current requirements in mind, what level of resistance did you use and make and model/part number?

Or am I just smoking something? lol

Enjoy the hobby as I do,

Hello Tyler,

It looks like the NTE part has the ebc not ecb lead pattern like the 2SA606. You might want to make sure you can swap leads without adding lead length. (Though it is being used for a pass transistor, it has a pretty high frequency bandwidth.) Couldn't find info on the L at the end of the part number. You may be able to find an actual 2SA606, if you have to. Or you can go the extra board route if that is simpler.

On the TS-520SE the -6v is generated by a simple resistor/zener shown on the schematic lower left. That is labeled R21 on the schematic for the 520SE. It is so basic it is easily overlooked on the schematic.

73,

Roger (AE3RT)

Hi Roger,

Good point, unfortunately (again) I overlooked the ebc/ecb and already ordered 3 of them. I will try and make it work. The one currently on the board has insulators on each leg, I suppose in a worst case scenario I can do the same if I have to swap the two legs.

Parts should be here next week, I will let you know how it goes!

I still cannot see R21 on the schematic. I see the -6 line with the resistor and zener diode, but it's labeled R23 on my schematic. Unless I'm looking at it wrong, which is a possibility :)

Topic: 41132 Message: 41746

I've used NTE replacements where the NTE lead orientation is different then the original transistor leads.

The first thing is to remove the bad transistor. This can be done using small wire cutting dikes, cutting the leads. Once the leads have been cut and the body of the bad transistor is out of the board you should see the remaining lead that can be removedusing Hemostats to grasp the leads then heat the foil side and gently pull the lead from the board. Once all leads have been removed, remove the solder from around the lead holes so the holes are free of solder and light passes freely through the holes. I use a solder sucker then check the holes using a bright flash light. If all the solder is removed the holes will appear clear and "round".

Next, inspect the new transistor, identify each "E"mitter', "B"ase, and "C"olector leads. Draw a picture on a piece of paper showing the leads so you don't forget. You would be surprised how many transistors get installed incorrectly because the person "forgets" which lead is which and "assumes" they have it right but find out later they made a mistake. By that time it's too late.

Next, carefully bend the leads, ensuring they do not short, so the transistor can be installed with the correct leads in the correct holes. This is where the "Xray" pictures in the service manual come in handy. The board MUST be thoroughly inspected so the person installing the transistor KNOWS which holes are for the "E", "B", and "C" leads.

Once the transistor leads have been oriented properly and pushed through the "Correct" holes, AGAIN, closely inspect the leads to "ENSURE" they are NOT shorted, holdthe body of the transistor with you finger, applying just enough pressure to ensure the transistor does NOT fail, then turn the board over and bend the leads "slightly" so the transistor cannot failout when you remove your finger. Connect heat sinks to the lead(s) on the component side for the leads being soldered, attaching the clips as far from the body as possible. This may not be easy but it will protect the transistor from excessive heat that can easily damage the transistor.

Next, apply solder to the soldering pencil's "Clean tip",just enough to coat the "tip", then apply heat to the lead and PC foillead pad. Apply solder and when the solder flows freely onto the foil pad and the lead remove the heat and allow the solder to cool and solidify. Move the heat sink to the next lead and repeat the process until all leads are soldered.

Turn the board over, remove the heat sink clip, and thoroughly inspect the transistor leadsto ensure the leads are not shorted against each

otheror to another component(s) and the body of the transistor is not shorting to anything else. If all is okay then clip the excess from each lead on the foil side of the board.

Next, thoroughly inspect the foil side, looking for solder bridges, even a very thin trace of solder that you can't see that is not suppose to be there can result in a short. I use a bright flash light shinning directly at the component side while looking through a magnifying glass at the foil side. I've found more shorts plus cracks in foil runsusing this method.

If all is okay then install the board and test.

I'm looking for a wiring diagram for the Shure microphone model# CR20SLE. I want to wire it up for a TS 820. The mike is a low Z type.
Robert.

Hello Tyler,

Yes, R23 would be correct. When I looked closely at your board picture, R21 is just an empty spot. You can see that the resistor you spoke of connects to D8 so it must be R23 as you said.

Hope all goes well and that replacing Q4 solves the issue.

73,

Roger (AE3RT)

Hi Robert, I am including a link here but first I have to say this there were many models of this mic, so read the entire page the link takes you to then check out the other models you might find that most had the same wiring just a different mic cartridge.

Good Luck Allan & 73

High Z microphones have a higher output level than a LOW Z microphone, resulting in lower gain design requirements in the audio amplifier the microphone is connected to.

LOW Z microphones, on the other hand, have much lower output level than a HIGH Z microphone, requiring higher gain design in the amplifier the microphone is connected to.

The use of the wrong impedance microphone can and will affect the transmitter's RF output level which also will affect the quality and level of recovered audio at the receiving end. You cannot overcome the impedance mismatch problem by turning the MIC gain UP!! The fix is to use a microphone with the proper impedance. I do not recommend using any LOW Z microphone with a transceiver such as the TS-820 that has a HIGH Z microphone requirement.

41752. BS-8 conversion to BS-5 ??

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Topic: 41752 Message: 41752

Hi All,

My search for a BS-5 to install in the SM-220 is fruitless.

Is there any publish work out there to re-work the BS8 I have to be consistent with the BS5 I need?

I can't find schematic anywhere for either..

Thanks
Archie

Thanks, Roger. That makes sense.

And Mike, thanks very much for your detailed write up, I have read it
several times and will follow it!

I will update this once the part arrives. Scheduled for next week, but
hoping it gets here on Saturday :)

Thanks Allen. I kind of figured a low z mike wouldn't work well. Maybe I need to change the element and see how that will work.

Hi Group,

In tuning my just purchased TS-530s I'm not sure what the Plate Current should be. I know for my TS-520 is 225ma.

Thanks
Rob

Topic: 41756 Message: 41758

Plate CURRENT IS NOT THE SAME and IT IS NOT 225 ma FOR A TS-520.

For GOSH SAKES we are ham operators. This is a technical hobby. Read your owners operator manuals and if still uncertain then come here and ask. It is all there in front of you. Your manuals should be dog eared.

TS-520, TS,520S, TS-520SE and TS-820 Transmitters are all rated at 160 Watts DC Input Power. You load these to.... "ABOUT 200 ma"

TS-530 and TS-830 Transmitters are rated at 180 Watts DC Input Power. You load these to.... " Reduce the Carrier Control setting if Ip is over 265 ma"

1. Where did 225 ma come from? Ken Kempski K4EAA in his FAQ section suggests that 800v X 225 ma = 180 watt dc input power and it is pointless to exceed this level as it wont make perceptable difference on the receive end of a transmission and loading to this level (assuming proper loading technique) can extend final tube life. Without saying it Ken was obviously speaking about TS-530 and TS-830 rigs as they are the only two models with 180 watts dc input ratings. He would not recommend loading to 180 watts dc input power on a radio designed for 160 watts dc input power.

2. Why are the early rigs rated at 160 watts dc input and later rigs at 180 watts dc input? I Do Not Know With 100% Certainty. What I Believe is that it is due to the switch from S2001A finals to 6146B finals. I Believe 6146B tubes have higher Plate dissipation ratings. I have never seen a S2001A Data Sheet and do not know there plate dissipation or any of there ICAS max ratings. If anyone has one please send to Gordon N6WK so he can post on his site.

3. Is there any difference in the HV power supply capacities? No apparent or published differences that I have seen. Maybe we can ask Bob Mansker to hack transformers out of these rigs and weigh them to see if difference in copper and iron? Transformer weight roughly corresponds to KVA capacity.

4. Sorry about my frustration. This is suppose to be a thinking mans hobby. You have to be able to read and read with comprehension. Lacking this ability you are in trouble. Very easy to just ask and expect an instant answer with out doing any modest amount of homework. Maybe it is a age and cultural thing? I prefer to help those who are willing to help themselves.

5. Lets stop putting wrong information out on this forum. Easy to just "Parrot" what you have heard. This is how tribal myths perpetuate. If you are going to respond do so as an "expert" or do so by qualifying your response. I will try to remember to preface my remarks by telling you what I "know" first and then what I "believe". Can be a big difference between those.

One of the worst things you can do is tell people what you know to be fact only to find out later you were wrong. Pity the poor Flat Earth folks!

41759. Kenwood TS900 external remote VFO Unit..

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-19 12:34:58 UTC
From: Behiels JeanPierre
Topic: 41759 Message: 41759

Hi Kenwood vintage users ;

Anybody who now if the external remote VFO of a old TS900 TRX is usable for spare parts for repair a old TS510 VFO.
Especially the dry shaft and wheels are they interchangeable ??
The bearing of the TS510 is totally shifted out (to mutch place between shaft and bearing).
I will use the wheels and shafts of a spare TS900 external remote VFO I have.
Maby someone has some experiences concerning this repair job and change of the mechanical drive shaft device of the VFO himself.

Regards Jean ON4AEF.

Hi Guys,

Just to add to Terry□s post.

We all have the best of intentions here to help everyone. It can be confronting sometimes to be told that you are wrong about something. We are all here to learn and help each other. We become better hams/people as a result.

Thanks for the info Terry. I have been a TS-520S fanatic for over 10 years and never knew that! So I will watch that plate current. My TS-520s (well both of them) still have the original S2001A finals from the 70s with 100watts on all bands. So I must be doing something right.

QUESTION:

If we replace the finals in a TS-520S with 6146B□s, is it ok to set to 225ma then?

Again thanks Terry. Learn something new everyday.

Andrew- VK2-XXL

Why waste time asking the seller for the manual when he can download the operator and service manuals, right now for FREE, at Grodon's website(see link below)??

Topic: 41756 Message: 41763

The 530 manuals, along with other Kenwood manuals, can also be found on
the Kenwood Yahoo Group website's "Files" section. The link below will
take you to the Files/manuals section but you have to log onto the
GroupFIRST.

The login information is the SAME information, username and password,
you use with your email client software to receive Group postings and
responses.

http://groups.yahoo.com/group/TS-520_820_530_830/files/MANUALS/

You cannot access the "Files" section using your emailclient, you MUST
use your webbrowser!

Andrew:

A very good next logical question. I have had many 520s on my bench with a variety of final tubes including 6146Bs. I have one here now.

I cannot give you a 100% answer because I do not know the KVA rating of the power transformer and have not evaluated the ratings of the HV rectifier diodes. I believe the HV VO8J diodes are rated at 1000PIV at 1 amp, but have not seen a data sheet.

My educated guess is that with 6146B finals in your 520, 520S or 820S you can go to 225ma with no ill effects on the HV power supply. I know plenty of 520, 520S and 820S owners who do that and have experienced no HV power supply failures.

I suppose you could monitor transformer case temperature but that would be very subjective.

In short I would have no problem running 6146Bs in my 520 and loading to 225ma. IMO proper loading and operating technique such as short key down times and reduced current for high duty cycle modes like PSK will do more to extend your final life than whether you load to 200ma or 225ma.

Terry,

You pretty much confirmed what I was thinking J

Of course, it would be silly to rip out a perfectly good set of S2001A□s and replace them with 6146B□s to get a few extra watts, but this pretty much is enough to convince me.

If anyone else knows about the ratings of the VO8J diodes and the power rating of the transformer, I would love to see that. But probably not really necessary.

I am determined to get as much life as possible out of my S2001A□s.

Andrew □ VK2XXL

Andrew:

I likewise would not pull the S2001As if have good RF output. I still see them from time to time on my bench. I would however buy couple of NOS 6146Bs or NOS 6146Ws from reputable supplier as spares. I like to rotate my spares in. Subject of much debate and no point wasting the space here. Just know that the day may come you will need to replace your original finals. Not very likely you will be able to find any S2001As and I am not ready to buy Chinese made 6146s at this time based on anecdotal I have seen.

Topic: 41756 Message: 41767

Terry,

Yes I have heard nasty things about the Chinese 6146B□s. I would never trust them, unless another manufacturer came along and did a good job. I actually do have a spare set of 6146B□s here, but getting a NOS set would not be a bad idea. Even a couple, so you have given me some persuasion there.

Anyway, very late down under. I□m off to bed, but will reply to any-more posts if necessary tomorrow.

Great talking to you again Terry.

Andrew VK2XXL

Subject: [TS-520_820_530_830] Re: TS-530s Plate Current

Andrew:

I likewise would not pull the S2001As if have good RF output. I still see them from time to time on my bench. I would however buy couple of NOS 6146Bs or NOS 6146Ws from reputable supplier as spares. I like to rotate my spares in. Subject of much debate and no point wasting the space here. Just know that the day may come you will need to replace your original finals. Not very likely you will be able to find any S2001As and I am not ready to buy Chinese made 6146s at this time based on anecdotal I have seen.

>
> 2. Add a pot to control the screen grid voltage (210A) of the 12BY7A Driver tube. Can add a fixed resistor to lower the screen grid voltage (start with approx 33k ohm) or add a pot. HeathKit used a 25k ohm pot as a Load control by varying the screen grid voltage of the 5763 Driver Tube in its DX-100. This results in having a "load control" that adjusts the level of RF output from the Driver stage to the Finals.

> >
> > Hi, I was recently thinking of reducing the output from either my 820 or 530 to a lower level, not quite QRP but around 10 to 25 watt level. It occurred to me that the easiest way to do this would be one of the following methods, one , move the HT tap on the transformer down to the 400v tag or ,two, remove the doubler and fit full wave IE 400-0-400 bridge rectifier. This will have some effect on the anode impedance but the tank circuit should easily be taken care of, what do you think and has anyone tried a similar thing. Moving the HT to the 400v tag is the easiest and simplicity itself to restore to original.
> >
>
Thanks Terry,
That's certainly food for thought, it just seems crazy to have 800+ volts on a pair of finals to produce less output than could be obtained from one. Reduced Ht would be easier on the associated components in the PSU as well. So far it's just an idea so I guess i'll kick it around for a while before deciding.

I just got an 820,supposed to have just low xmit.The final were smoking when I cranked it up. There is no bias control.On the x44-1150-00 bd there are two 470ohm add-ons to the foil side.One,on the schmetic is labled R56 is grded on both ends.I assumed it was shorted, but lifted one end and R56 is good. Why would you add a resistor to both ends of a grounded foil? I can't determine were it might mistakenly be used. On a better schmatic I downloaded from Douglas's site,dosn't show any such resistors.This is my first query, but probably not my last!

I just checked the original Service Manual and all the schematics I have here.
They all show (2) R56 resistors, one is labeled R56 and 47 ohms, the other is R56 and 470 ohms LOL
And I see the 470 ohm that is grounded on both ends as well. That doesn't make sense to me either.

I noticed that if you look at the Individual Board Schematic, neither of the R56 resistors are shown in that one.

I see no R56 in my schematic but I do see a R55 470K that I don't see on the N6WK schematic ?

The 820 documentation leaves a lot to be desired and the as-built configuration comes in a variety of forms. Ordinarily when you find a resistor between two pads like R56 on the RF board it would be in lieu of a wire jumper. They make R "0" ohm resistors that can be auto loaded via a machine on a assembly line for this purpose. Not typical to use a 470 ohm resistor to jumper two ground foils as you dont want any difference in potential on the ground plane.

Are you certain that C44 and T3 are both landed on the common and continuous ground plane foil and not one of them on an isolated ground "island"?

I would think C44 would be connected to the main ground plane. It and
R28 are the decoupling network for the AGC control voltage to Gate 2 of Q3. If anything it is possible that the cold end of the primary winding of T3 is not connected to the ground plane and is grounded thru the 470 ohm to C44 ground pad? This would provide two Source resistors in series with one being bypassed for the RF signal.

This would make more sense and would be called a "partially bypassed" source resistor. You do that to provide some level of degenerative feedback to control the gain of the mosfet amplifier. It may have been an after thought when it was found the stage had to much gain and/or distortion.

The foil view that I have in my service manual appears that T3 and C44 are both landed on common ground plane and no need for a jumper resistor.

I never noticed R56 before. Thanks for asking. Hopefully one of the 820 owners knows the answer.

Well I could not stand it any longer.

I removed the covers from my TS-820S and yes there are two 47 ohm (not 470 ohm)resistors on the foil side of the RF board and as reported the one associated with Q3 RF Buffer Amp does bridge ground to ground. It is also a little low in value to be an un-bypassed source resistor for Q3.

I cannot see any break in the PC foil trace under magnification, but I do note a pretty large amount of solder piled up near the ground plane end of this trace. It makes me wonder if the trace is cut under this mound of solder and the solder is bridging this cut. Why it would be cut and bridged with a 47 ohm resistor I do not know unless it was used to place a 47 ohm termination on Transformer T3?

As the original poster noted it makes no sense to bridge this ground foil trace with a resistor. Wouldnt it be nice to be able to speak to a Kenwood hybrid design engineer.

If I had a spare RF board I would remove the solder and examine the trace to see if it is continuous or has at one time been split. I have a good Hakko 808 de-soldering gun that would facilitate this inspection.

I will likely remove it and toss it. The schematic does not match the as-built config and no way to tell which is correct. Even if they did match it would not make sense electronically. It will be easy to measure receiver performance with it installed vs removed.

Roger, Mike, Alan, Terry, et all,

I went and picked up the replacement NTE part (I couldn't wait until next week for the parts to arrive, and found a place semi-local that had it). After carefully following the traces (using a flashlight on the backside of the board was an amazing help!), I got the new part soldered in. So far, it looks like this was indeed the source of my problem (Q4 on the FIX-AVR board)!

Hopefully I'm not jumping the gun, but I've used the radio and let it cool down several times and it has not gone deaf a single time! So far I'm a happy camper!

Thanks again to everyone for the patience, help, and sharing of knowledge. I enjoyed this small repair (albeit, you guys did all of the work), but it makes me want to get another one and try figuring these types of things out myself.

73!

Subject: Re: [TS-520_820_530_830] Re: ts520se sidetone question

Roger, Mike, Alan, Terry, et all,

I went and picked up the replacement NTE part (I couldn't wait until next week for the parts to arrive, and found a place semi-local that had it). After carefully following the traces (using a flashlight on the backside of the board was an amazing help!), I got the new part soldered in. So far, it looks like this was indeed the source of my problem (Q4 on the FIX-AVR board)!

Hopefully I'm not jumping the gun, but I've used the radio and let it cool down several times and it has not gone deaf a single time! So far I'm a happy camper!

Thanks again to everyone for the patience, help, and sharing of knowledge. I enjoyed this small repair (albeit, you guys did all of the work), but it makes me want to get another one and try figuring these types of things out myself.

73!

41779. Need (X44-1360-00) RF board with band-switch for TS-830S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-20 02:34:29 UTC
From: Bob - K2KI
Topic: 41779 Message: 41779

Hi all,

I recently acquired a TS-830S which is pretty ok cosmetically. It seems to have had the HV caps and screen resistors changed. The only problem is that the RF board with band-switch is MIA. Does anyone have one they would be willing to sell?

Please drop me a note if you can help...
73...

Subject: Re: [TS-520_820_530_830] Re: ts520se sidetone question

Roger, Mike, Alan, Terry, et all,

  I went and picked up the replacement NTE part (I couldn't wait until next week for the parts to arrive, and found a place semi-local that had it). After carefully following the traces (using a flashlight on the backside of the board was an amazing help!), I got the new part soldered in. So far, it looks like this was indeed the source of my problem (Q4 on the FIX-AVR board)!

  Hopefully I'm not jumping the gun, but I've used the radio and let it cool down several times and it has not gone deaf a single time! So far I'm a happy camper!

  Thanks again to everyone for the patience, help, and sharing of knowledge. I enjoyed this small repair (albeit, you guys did all of the work), but it makes me want to get another one and try figuring these types of things out myself.

73!

Good job, Tyler.

Glad you have your radio working again!

73,

Roger (AE3RT)

41782. The reason we are in this group

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-20 07:33:06 UTC
From: Avguy
Topic: 41782 Message: 41782

Just a reminder, not everyone has as much expertise in some areas as some folks. Some things are not obvious to everyone. The reason we joined this group is to learn and share. When I taught middle school kids, I always encouraged them to ask questions. There are no stupid questions except the ones that didn't get asked. New members need encouragement and direction to find all the resources that are available here, not criticism! Just my 2 cents worth.

41783. TS 830s no output

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-20 14:55:14 UTC
From: Gary Yancey
Topic: 41783 Message: 41783

During tune up I am able to dip the plate and load it to 225ma when I switch to rf to adjust to max power out the radio meter pegs and there is no output indicated on the wattmeter. I loaded up into a dummy load and I replaced the jumper to be sure that was not an issue. I also loaded into the antenna all with the same results. I was told this may be the antenna relay. I found a relay on the bottom side next to the finals but not sure if this is the correct one. I thought there was a switching relay and a seperate antenna relay. The schematics are not very specific regarding the antenna out. Just wanted to see if anyone else has had this problem. A point of interest, the radio tuned fine a couple of weeks agao.

Gary

41784. Re: The reason we are in this group

Ken: That old adage is baloney. There are plenty of "Stupid" questions.

1. When you ask without making any effort it is a Stupid question.
2. When you ask without cracking a book it is a Stupid question.
3. When you ask and just want the answer and dont care about the basis, derivation, and/or the why behind the answer it is a Stupid question.

Teachers and parents face all of the above daily.

I raised 5 children and it was not acceptable to ask what the answer was on the homework questions and admit you had not read the chapter. Books were not left in school lockers at my home. They thank me today.

I was not criticizing the question and hopefully no one is scarred for life. I was criticizing not doing your homework. Not reading the operating manual tuning/loading instructions, not reading the service manual circuit descriptions, not studying the block diagrams and schematics, not searching the forum archives. If you own a hybrid and expect to operate and MAINTAIN it then getting your hands on all the available reference documents and devouring them should have been your first step. All readily available and free. Was no forum when I started and no Kenwood Elmers. Thank god for ARRL Handbook.

I was also criticizing Parroting answers and shooting from the hip without thinking.

Our Education system today must not have very high expectations for our kids. I guess it is just too damn hard or teachers are too busy teaching the tests and not fundamental skills like reading, writing, public speaking, computer literacy, diagnostic/analytical skills, and critical thinking. I am afraid I would be hurting little Jimmies feelings just about daily.

Here is how to ask a question:

My operating manual for my TS-520 says to load to about 200ma. I notice on this forum people advise to load to 225ma. Why is it OK to exceed what my manual states? Also, what is the basis for either one of these two limits? What happens if I exceed these limits? (or something similar)

For the most part members here are adults and should be motivated to learn for very different reasons than kids and should have much better learning habits. I acknowledge that not everyone learns the same way. Tell-Show-Practice-Feedback is a nice model for knowledge and skill items. Unfortunately this forum doesnt support the complete model.

I meant no personal attack on anyone. In fact I looked at the QRZ bio page of the individual that responded that all had same plate current and found that he had made his own "luck" in life and can be proud of his accomplishments. I do not know him but admire him. I think he just pulled the trigger too quick or perhaps he actually thought that and had never researched it.

This is why so important to tell what you know and not what you think, feel, or believe. Can be hard for the learner to sort the facts from the BS.

Since I am a curmudgeon I apologize for this lament. The dumbing down of America is driving me nuts. This is no place to rant about it.

Terry K9TW

Hello All,

I'm not bothering to read the entire thread here, :-) but I sense that its just a very common phenomena on message boards. Someone always is "flamed" for being a little less diligent with their own research. I'm guilty. Also what seems common is banging the heads of folks who don't read the manual.

Thankfully, these dust-ups only happen on message boards and not on the air, right? (that's a joke).

I appreciate the list, and those who moderate it.

Thanks,
Archie

I don't feel as though anyone here has done anything wrong.

Terry was just very concerned and wanted to help. I could see that.

I think we all can get a little grumpy every now and then over certain
things but as long as no personal threats or insults are made, I'm all cool.

If I talk about something and it's wrong, I would hope that Terry or someone
else would pull me up right away!

Love this group.

Andrew

I think there's a happy medium between asking for an answer without doing any research or testing/inspection and expecting
everyone to re-invent the wheel. I've got many years in the home entertainment repair business and it was very common for
the various repair shops to call one another and ask for some direction when they had expertise on one brand over another.
We specialized in RCA and Zenith while other shops sold and serviced Magnavox, Sylvania or other brands. It's the same
with radio equipment. Each brand has it's idiosyncrasies and shortcuts for troubleshooting. I don't think it's productive to rant
on anyone. There are better ways to get a point across. At 70 years old, I have a major problem reading the crappy Kenwood
schematics in the available downloadable manuals and our brains don't work as well as they used to so lighten up.

My two cents worth.

I also agree. We need to know the WHY and How as well as the answer.
Otherwise, nothing or very little learned!

BTW, Welcome back Terry

Joe,

Are the 6 and 2 meter converters included and installed? That makes a difference in the price for the receiver.

I bought and still have aKenwood R599A receiver with both 6 and 2 meter converters installed for $185. The only problem it has is it "warbles" when tapping lightly on the desk and/or operating desk it sits on. I haven't gotten around to fixing the warble problem but I will this summer. It's a great receiver, excellent noise limiter, and it's very sensitiveon all bands.

Mike: This one also had a warble when table tapping and tuning. Remove the top of the VFO and then unscrew and lift up the printed circuit board. This will allow you to peek in and see the front variable cap bearings and also the area at the rear with the shaft grounding connection. A diabetes syringe with a drop of two of DeOxite cleaned the grounding connection and a little sewing maching oil on the front bearings made the VFO as smooth as a babys fanny!

  Also set the radio on its back with the VFO shaft pointed up. One drop of machine oil around the concentric shaft and let the oil flow down.

Hope this helps out.

Ken: That old adage is baloney. There are plenty of "Stupid" questions.

1. When you ask without making any effort it is a Stupid question.
2. When you ask without cracking a book it is a Stupid question.
3. When you ask and just want the answer and dont care about the basis, derivation, and/or the why behind the answer it is a Stupid question.

Teachers and parents face all of the above daily.

I raised 5 children and it was not acceptable to ask what the answer was on the homework questions and admit you had not read the chapter. Books were not left in school lockers at my home. They thank me today.

I was not criticizing the question and hopefully no one is scarred for life. I was criticizing not doing your homework. Not reading the operating manual tuning/loading instructions, not reading the service manual circuit descriptions, not studying the block diagrams and schematics, not searching the forum archives. If you own a hybrid and expect to operate and MAINTAIN it then getting your hands on all the available reference documents and devouring them should have been your first step. All readily available and free. Was no forum when I started and no Kenwood Elmers. Thank god for ARRL Handbook.

I was also criticizing Parroting answers and shooting from the hip without thinking.

Our Education system today must not have very high expectations for our kids. I guess it is just too damn hard or teachers are too busy teaching the tests and not fundamental skills like reading, writing, public speaking, computer literacy, diagnostic/analytical skills, and critical thinking. I am afraid I would be hurting little Jimmies feelings just about daily.

Here is how to ask a question:

My operating manual for my TS-520 says to load to about 200ma. I notice on this forum people advise to load to 225ma. Why is it OK to exceed what my manual states? Also, what is the basis for either one of these two limits? What happens if I exceed these limits? (or something similar)

For the most part members here are adults and should be motivated to learn for very different reasons than kids and should have much better learning habits. I acknowledge that not everyone learns the same way. Tell-Show-Practice-Feedback is a nice model for knowledge

and skill items. Unfortunately this forum doesnt support the complete model.

I meant no personal attack on anyone. In fact I looked at the QRZ bio page of the individual that responded that all had same plate current and found that he had made his own "luck" in life and can be proud of his accomplishments. I do not know him but admire him. I think he just pulled the trigger too quick or perhaps he actually thought that and had never researched it.

This is why so important to tell what you know and not what you think, feel, or believe. Can be hard for the learner to sort the facts from the BS.

Since I am a curmudgeon I apologize for this lament. The dumbing down of America is driving me nuts. This is no place to rant about it.

Terry is spot on with his response. His knowledge and many others up here is a gold mine. We are very lucky they take their time to convey their knowledge in long emails. It takes much of their time to read and respond to these questions.

One should take time to try to understand the information on hand and then ask questions. They don't have time to answer questions about stuff in the manual we should have read.

I have a great interest in learning to tinker on hollow state radios and the test equipment. My situation is that there is no one within 200 miles that is versed in this technology.

I have learned to appreciate the knowledge Terry, Mike, and many others provide.....

Hi Joe,

Thanks for the tips. The VFO warble is not caused by dirty VFO variable capacitor shaft to frame connection or the shaft bearings but rather physical mounting of a component or two inside the VFO.Physical stability of components in the VFO is very important so environmental vibrations don't affect the VFO. I suspect a previous owner may have performed some work in the VFO which may have caused this problem. I'll start work on the VFO later this spring when I finish a few other projects I'm working on.

Topic: 39914 Message: 41803

For information G3OBU call sign belongs to a former ex british serviceman who has been a SK since 1960, John the current user of the call sign is a PIRATE STATION and has no right using this call, he has been removed from qrz and other databases for this reason.

SO BEWARE

Thanks

41804. Re: [TS-520_820_530_830] Hello Everyone TS-820S band switch knob wanted.

Hello Robert, I got it for $300 and seems to work well no drifting. I used it for over an hour on 40 meters.

41807. KENWOOD HYBRID USER NET (April 21st, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-21 18:44:03 UTC
From: mvgilger
Topic: 41807 Message: 41807

The Saturday's net on 40 meter we had 19 stations checking with good band conditions. There were 5 new stations checking in, W3OKC, KC8YY, KD2DIG, KF4WGR, and KE2MA. Out of the stations checking in, there was:

7 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 10 stations checking in under very poor band conditions. We had 2 new check-in, WZ7E and VE4AMN.

Out of those, there was:

5 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87

March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

Hey Everyone,
I'm going to part out one of my TS-830S's.

Everything works good EXCEPT for the IF Board.
As of today the radio is complete, powers up and all the good stuff.

I swapped out the IF Board to test and the rig worked as it should.

If you're interested in any parts please send email to "my call at arrl.net" or "stephen at mycall.net". I never check my ymail account as it has become a big spam folder.

I do take PayPal and Postal MO only. My QRZ address is good.

Thanks,
Steve - AE2S

At one point the Canadian jerk was flaming on about overthrowing the US
and bombing people, so I recorded some of his rant in the hopes that I could
get Canada's equivalent of Homeland Security to hunt him down and kick in
his door. I even reported some of the stuff to the ARRL. But nothing ever
happened.

BUT, if one of US ever slipped and dropped the "F-Bomb" you can bet we'd
get called on the carpet.

Report what you heard, especially the bomb threat, to:

http://www.dhs.gov/if-you-see-something-say-something-campaign

It probably will do nothing to get him off the air, but it will put him
on the list of threats. It will put him in the radar of the US
government and maybe cause him a little grief an unwanted publicity.

Hello All,

My nu-2-me TS-530s is on its way and I am researching microphones that would be a good match.

I was thinking about the relatively new Heil HM-12, but I might need a higher impedance mic, I believe that the HM-12 is for lower impedance applications.

Of the vintage microphones, or the newer ones, does anyone have a suggestion for one that works exceptionally well with the 530s?

Any input would be appreciated!

I am excited to be a part of this group, and to get started with what appears to be a great rig.

Thank You!!

Tom

I have a GE EM28A (Shure) microphone that works rather well with my TS-830S Kenwood in which I have received many complements on the audio. The only fault that this mic has is the ding that is on the grille. Recently,I purchased a very nice MC-60 mic that really matches the color scheme of my radio more so than the GE(Shure) microphone does. At this point,I am using the MC-60 on my rig. 73 DE KI4OJG.

Tom,

The TS-530's operator's manual can be found and downloaded, free, at the following link:

www.n6wk.com/kenwood/

Go to page "3" in the 530's operator's manual.

The Heil HM-12 specification sheet is found at the following link:

http://www.heilsound.com/amateur/products/hm12/productsheet.pdf

Go to page 2 of the specification sheet.

You will notice the Heil HM-12 impedance (1000 ohms) falls within the TS-530's 500 to 50,000 ohm range so it will work fine with the 530. I don't know why you would think/assume the 530's microphone impedance is high but if you were told by someone it was then you were told wrong.

The Shure 444 data sheet is found at

http://www.foxtango.kc9foz.com/FT101/Shure%20444.pdf

Note on page 2 Shure states the 444 to be a "high impedance" microphone
which clearly indicates it will work with ANY of the Kenwood hybrids
without any impedance changes/mods to either microphone and/or transceiver.

The Shure 444D is a dual impedance microphone and the data sheet is
found at:

http://www.radiomanual.info/schemi/ACC_microphone/Shure_444D_user_IZ3EOU.pdf

If the Shure 444D impedance setting is set to "high impedance" then it
will work with any of the Kenwood hybrids without any impedance
changes/mods to either microphone and/or transceiver.

Unfortunately Tom, who ever told you the TS-530 had high impedance microphone specs, obviously did not take the time to verify their information which ended up misleading you.

Agreed. Just get a Kenwood MC-50. I use two MC-50s on two Kenwood TS830s with excellent reports on audio quality. They can be gotten off Ebay or at local hamfests.

Just line up the red dots on the connector side of the cable and you should be in business. Works for me.

Enjoy the hobby as I do,

73,

I'll second the MC-50 suggestion/recommendation! Classy microphone now and in its day..nothing but good reports with it. Set to HIGH impedance, it will work with any of the Kenwood hybrids. With which, by the way--I've become a little obsessed. My collection now includes a TS-520, a TS-820S, a TS-530SP, and a TS-830S. :)

(I have little issues with 2 of the radios (TS-820S and TS-530SP) that I'll ask for help or opinions in different/new threads.)

41825. TS-820S "Send" button question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-22 20:04:54 UTC
From: Mark L. Hammond
Topic: 41825 Message: 41825

Hello all,

A few weeks ago I bought an amazingly clean TS-820S. The knobs and front panel were so clean I didn't even have to clean them, and the inside was equally clean. Score!

Now, the non-technical question of the day :)

The only thing I can find wrong with it is the "Send" button is "loose." It's like the plastic toggle cover is no longer seating on the actual switch--but I can't say for sure whether it's just the plastic toggle/cover, or if the actual switch underneath is actually bad.

I can press it "in" and it works better, and wiggles less, but it's clearly not right. The switch functions, which leads me to believe it's just the press on plastic cover...

Does anybody have any "tricks" in figuring out if I need to replace just the cover or the cover+switch? Of course, removing the front panel is the obvious way--but I'd like to have the actual replacement part(s) on hand before taking it apart...

Neither part is what I could consider to be "cheap" and I don't have any spare covers or switches!

Thanks,

--

Mark,

  Welcome to another common problem of the KW hybrids. The "paddles" have two long fingers on them that go into the front of the switch.
When one gets broken, for what ever reason...the "paddle" will do just what you describe.
There is a guy who is selling replacements on ebay.
They are not exact copies of the originals...but very close and very functional replacements., or Bob Mankser...ke5ftf..may have some
                    It is possible to remove the "paddle" from the front by grasping with padded pliers and pulling straight out. I doubt the the switch is "loose" inside...but by removing the "paddle" from the front...you can check the switch without going through the whole front panel removal

41828. Need some help with an RF board from TS-830.

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-22 22:53:40 UTC
From: bartbrummans
Topic: 41828 Message: 41828

First off...
I'm not an electronics engineer by any means, my education on that was two years of schooling, learning on my own, and poking and prodding.
But I enjoy it, and it keeps me busy.

So..
I've gotten myself into a TS-830, but it had a weak (deaf) receive.
Got the diagram and researched the net for possible causes.

From what I've found, it could be L41, D2, Q1.
D2 checks fine (with multimeter)..
Q1 was replaced...

I have some receive now, but only very strong signals move the S-meter.
Compared to my other radio, this TS-830 is still "deaf" to speak of.

Now here is some "backwoods" diagnostics...
If I touch the tabs of VC-2, the noise level increases drastically and the S-meter will start to jump up.

This leads me to believe that the problem lies somewhere between L13 and the Ant input (TP1). Any input?

Could L41 be "bad" but still let strong signals through?.
What is the best way to test L41? (What readings should I see?)

Mike, Terry, and other gurus on this group site who are continually tasked with answering the same questions over and over, I would make it mandatory for joining the group that one must read the files section of the group site for this information before they are approved.

Not meaning ill will on anyone, but this topic has come up about every 2 or 3 months it seems. Perhaps a simple FAQ section would be easier to go through than the entire files section, but a listing of acceptable microphones in a FAQ answer, a tune up link and or quick description in a FAQ answer, a paint answer in a FAQ answer, a knob or VFO removal, a cathode resistor check/replacement, or .... in a FAQ answer. I do believe it is the responsibility of someone participating in a technical avocation to take it upon him or herself to know how to do basic research on this. If nothing else a google search should provide dozens of answers if one only took the time to look it up.

Off my high horse now. This is too good a resource and the best of the guys on this site that work with repairing and aligning and rebuilding the Kenwood hybrids don't need to answer the same question time and time again. I would rather keep these guys on tap for when things get really sticky.

The paddle has the 2 long fingers but seldom break...
The paddle also has two small keeper tabs inside that tend to break off or crack, thus a loose paddle...
If you can remove with padded pliers then gently touch the small keeper tabs, they should be stiff... If one side moves then put a dab of JB-Weld Quick from the small tab to the button body...
I sell the paddles for $6.00 each plus my cost to mail ($2.00)...
Hope this helps...
Bob

Thanks Bob and Joe.

Joe, confirming that I could pull it off was a great tip. I was SOOo tempted, but resisted until I asked here :) I hated to break something.

I did pull the paddle off, and it has only 1 of the long tabs. I actually swapped with the NB paddle, since the SEND button gets used a whole lot more. They come off easier than they go back on (with front panel in place), that's for sure!

Thanks, Bob, for stocking such parts. I'll contact you off list sometime soon and order a few...

Well, with nothing to lose, I pulled out L41 and it is shorted across all pins...

Where can I get the wire that is needed to rewind it?
Also was there not a fix from KW to guard against transients?...

I am having the same problem but with a slight variation. The L41 will slightly tune but not peak the 160 adjustment for which it is intended. And I have low receive on 160, 80, and 40.

I have studied all the posts for L41 and found one person who noted the slight tuning of L41, but I don't think he got a reply. L41 looks perfect (I have had it out a couple of times to inspect it) so didn't rewind it. I did make some measurements on it and it still seemed fine, but I don't have them available.

I am also interested in the readings it is supposed to have. L41 one looks perfect with bright copper wire with no shorts between the primary and secondary.

I went over the RF board in this area of interest and resoldered everything I could think it needed but had no success solving the problem.

Q1 is good, signals are good if I bypass L41 as per troubleshooting instructions.

Bart,

Gordon...n6wk...of this board has rewound a few....I have done one...the wire is #42 enameled copper...real fine stuff...you will need
lots of magnification and bright light..and STEADY hand! Go SLOW and take close-up digital pics or make good notes.
Go to: k4eaa.com and scroll through the FAQ section until you find the section on L41.

This web site belongs to Ken Kemski...a wealth of knowledge on KW hybrids

Have a look in the file section if you have to go through the horrible task of rewinding L41, make sure you have plenty of time and patience! Have a look at all the fingers on the wafer switch on the RF board and turn through its range, making sure all fingers touch lands. One thing I have found in the past is the SO239 on rear panel may have broken wire connecting as these panel mounts work loose. Remove and reattach all molex connectors on RF board, use a little deoxit to ensure they are clean and have good electrical connection. If you have to remove board have a look at the foil side where molex connectors connect to board, this is a typical area of issue as the pins dont always have good electrical connection and have a tendency to be cold joint, if there is a cold joint remove old solder pull pin out give sand and then resolder using good tin\lead solder, be careful as these board have a tendency to lift pads and tracjs when heated. turn radio over and with radio turned on in receive , next to the final board there is a tin shield that has the antenna relay, remove the shield and give relay a tap, if there is any significant difference in receive maybe the antenna relay. Whilst your at it maybe remove all moelx connectors on AF, IF and PLL boards, becareful when removing these molex connectors, try not to wabble them as this can crack solder. These are the basic steps to try before removing L41, Q1 etc. the 3SK73gr dualgate FET is still available new.

Has anyone found a good substitute for L41? That is, has someone measured inductance and range on the coil so that an acceptable part could be more easily fabricated than rewinding the original part with extremely fine wire, etc. Magnetic materials have progressed a lot since the early 80s such that a 160M coil of yore could be very different if done today. Just a thought but if a simple substitute that is easy to manufacture in the hundreds or even by the operator hand winding one, a solution for a shorted or open L41 could be a lifesaver and much less frustrating than using ultra fine magnet wire.

Does anyone know the specs on the coil? I know a lot of magnetics companies who would be happy to provide me core samples.

Cheers
Larry

Members;

I have obtained a old TS510 transceiver without the external VFO-5D.
I will make a try with this TRX without the use of this external VFO.
Did I also have to put a bridge between pins 8 and 9 of the 9 pin remote VFO connector on the back of the transceiver ??
In the user manual of the later TS515 model there is some attention to the 9 pins connector on the banck,but in the manual of the earlyer TS510 I could not find any information on this subject .. ??
I could do the same has on a TS515 but I am a little bit scared to burn this nice set..
I look forward if someone has some details about this use.

Regards Jean ON4AEF.

Not enough to check for shorts from Primary to Secondary. One shorted adjacent turn on Primary or Secondary will significantly alter the inductive reactance of the winding. DC ohmic resistance wont show a turn to turn short.

If you have the transformer out couple of ways to test it. One is measure the inductance with LCR bridge and/or excite it with calibrated sig gen and confirm the voltage step-up ratio.

Here are the values from my notes. Suggest you check with Gordon to see if he has recorded values as well.
1. Primary 6 turns #42, 0.30 ohms, 0.850uhy
2. Secondary 26 turns #42, 1.00 ohms, 15.41uhy

Inductance was measured with the slug tuned core approx 1 turn from top of former.

I have looked at Toko IF transformer catalog and havent found any sub. Did not do exhaustive search.

In addition to losing L41 and Q1 I have seen shorted L1 2.7uhy choke in the TS-830 BCB filter. If this choke shorts or inductance varies it will shunt signal to ground. I have not seen bad L3/L4 8.830 traps.

Transients generally caused from two sources.
1. ESD (near by lighting)
2. Inadvertant transmit RF

Can use an external Front End Saver. People who work multi-transmitter contest stations use these devices. Also those who use separate receive antennas (like a Beverage on 160M) use front end savers. These devices use high speed reed relays to disconnect the antenna and ground the receiver in TX mode. Commercial units are available or can home brew.

See KD9SV and OK1RR for examples.

There is not much room inside the rigs to install passive devices like series lamp bulbs and back to back switching diodes. This method was used in 60s and 70s rigs like the Drake receivers. Not sure how well they actually worked. Have seen the series lamp bulbs burned out.

Also there are more modern devices like TVS Diodes(see Little Fuse catalog), PIN Diode Limiters (see AVAGO catalog)and Gas Discharge Tubes (see Mouser 652-2027-09-BLF). Again problem is room on RX side of TR relay to install these.

You can place a Static Bleed on the rig buy placing a Coax Tee on the rig S)-239 and at the open end of the Tee solder two 1meg ohm 1/2watt resistors in parallel. Wont affect TX or RX operation. Wont help with inadvertant TX RF. Some recommend using a RF choke in lieu of the resistors but I would not as all chokes have series resonances that may fall in ham bands and transmit RF can burn up the choke.

Greeting all....I need a pep talk ! I have a couple of 820's on the bench with the same problem....No digital displays operating ...nothing ....Went throught the service manual and saw at the DG-1 trouble shooting page....to check voltage at the "cof" terminal....stated that if 1.2v shows there...a defect in the PLL circuit is the cause....that is the case with both radio's...both show 1.2v.....spent the last few days with schematics....tracing circuits and testing voltages and have not found a resolution....When the "cof" wire is pulled out of circuit...the displays lite up properly....the service manual states that this means the counters work normally....I have limited experience with trouble shooting....I have some equipment here VTVM...scope ...signal Gen....and use it poorly....but can use it....Can someone steer me in the direction to start checking further....?I really enjoy being self reliant but realize when I need a little push from those with more experience......Thanks all..

Regards...Wes....VA6DWH

I forgot to mention about commercial units like Polyphaser, ICE, and Alpha-delta. I have these in all my coax lines at my antenna entrance panel. So far no lightning induced damage in my TS-830s. I also use Alpha-Delta antenna switches at the operating position. These are pricey but have internal GDT and a ground position. Of course, can also leave coax disconnected off rig when not in use.

Some folks home brew their own version of the ICE unit. Here is a website that shows the schematic for the internals of the ICE unit.

http://www.iceradioproducts.com/33.htm

Can build in diecast box with SO-239 on each end. Here are the values.
1. Shunt resistor is 1 meg ohm
2. DC blocking cap is .01 uf
3. Gas discharge tube can be purchased from Digi-Key, Mouser. Digi-key has a good primer to help you size the GDT.
4. RF choke is 100uhy.

L41 must be a 'special" or custom wind.....

Well, I've found some #42 enameled wire...

I'm presuming that the 6 turn side is the Primary ultimately connected towards the Ant, the 26 turn secondary towards Q1.

When winding the transformer:
- Primary first or secondary?
- Any particular direction that the windings have to go?

I did find some Toko replacements on ebay, wrong turns but I need a case and slug...

What about L13? How "compatible" is this? (just curious....)

Tom

I've had very good results / reports with the Kenwood MC-60 Mic...
New these are $150 or so (Mic and base) at R&L, or flea-bay...

Normal configuration is for an 8-pin radio, but with another cord, or plug, or adapter they easily work with the 4-pin rigs..

Right now I have a 530, 820, 830, 940 all using this mic..

An MC-50 will play nice as well, and it's a direct plug-in.

It all depends on your budget. Everyone (including myself) will have an opinion on what may be best....

BTW...the 530 is an awesome solid performer...don't know if this is your first run with ham (amateur) radio, make sure your antenna set-up is good. Great radios on poor antennas won't perform.

Good luck..

The MC-60 is the same as the MC-50 but the MC-60 has additional controls on the stand that are not useable with the hybrids.

MC-50s are a common item on eBay.

I have both.

Beginners may not realize that their answer is in the manual or in the
files section.
All that is necessary is to write: "Your answer will be found in the files
section at
such and such place."

If you keep answering the repetitive questions, you will just encourage
people to
ask them again and again. This is the expert's call.

Bart:

I have only rewound two of these. Gordon is the expert. Check with him before proceeding.

From my memory you wind the 6 turn primary on the bottom of the spindle and the 26 turn secondary on the top. Try not to scramble wind. There will be some overlap. The end windings will cross over to make the connections. I dont see in my notes if I wound CCW or CW direction, but I think CCW?

I try to use solderable magnet wire if I can get it. If not I melt a pool of solder on pine board and wire end thru it with light pressure from the soldering iron tip and it does a good job of removing the insulation and tinning the lead.

Just need a magnifier and steady hand (no coffee!).

This transformer is approx 4:1 step up ratio so yes 6 turns is primary winding that cold leg is grounded. The middle pin of the three has no internal connection.

If possible measure the inductance of each winding and/or excite with your sig gen and look at output level with RF millivolt meter or O-scope before installing back in the rig. Not fun to have to pull board again if it doesnt work.

I have never removed and tested L13.

Input voltage is 261 vdc pin 7 174 vdc voltage divider is good and bypass cap. I pulled the board and tested with just 210a connected and all is well. Acts like its keyed or something?

41851. Stuck Transmit Coil

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-23 12:34:43 UTC
From: paul.nussbaum
Topic: 41851 Message: 41851

With the help and advice from a previous thread, I was able to fashion one of my adjustment tools to turn all of the ANT and MIX coils fine (and perform the adjustment procedure for those).

I used a hard plastic chop stick and sand paper to fashion an adjustment tool for the larger slots in the transmit coils that works for all of them except 3.5MHz, which won't turn. I did the adjustment for all the others including T1 on RF and T10 on IF in conjunction with the 1.8MHz TX coil adjustment.

I dabbed that 3.5 TX coil top with a q-tip of WD-40 and let it sit for a day, still wouldn't turn, gave it another dab and another day... still won't turn.

It is not cracked or broken, just tight... tight enough that the very tip of the chop stick came off and is now resting in the little slot; I'll fish it out shortly...

I think it does need adjustment because 3.5MHz tunes up "differently" than all the other bands - LOAD control goes full clockwise without reaching RF peak. All the other bands peak LOAD in the center range.

Here is a tuneup snapshot of the bands to provide some data.
All /x figures are 12 hour clock face knob positions except Plate.

29.5MHZ 95W @ 210ma Load/11 Plate/28 Drive/2 Car/11:30
29MHz 105W @ 210ma Load/11 Plate/28 Drive/12 Car/1
28.5MHz 80W @ 210ma Load/11 Plate/28 Drive/11 Car/11
28MHz 80W @ 210ma Load/11 Plate/28 Drive/10 Car/11
21MHz 80W @ 210ma Load/12 Plate/21 Drive/12 Car/9:30
14MHz 80W @ 225ma Load/12 Plate/14 Drive/11 Car/10:30
7MHz 75W @ 225ma Load/11 Plate/(3.5!) Drive/10 Car/9
3.5MHz 65W @250ma Load/CW Plate/3.5 Drive/11 Car/10:30
1.8MHz 65W @250ma Load/1 Plate/18 Drive/11 Car/10

Is this stuck coil causing low power output on the lower bands around 3.5, as well?

Any ideas on how to free up this coil?
Something other than WD-40?
Application of heat?
Or spray it with cold?

Thanks,
Paul
AD5FT

I went back through my Emails. The Drawing was done and shared with me by Joe WW8X back in 2011.

Thanks Joe !

The TS-820 and the TS-820S can both operate without the digital display working.

Did you check the rear 9 pin remote VFO socket for either the factory jumper plug or a jumper wired between pins 8 and 9 before you started taking voltage measurements?I didn't see any indication that you did this check in your initial posting. If you have not then that should be the first place you start before venturing into taking voltage measurements.

If the factory jumper plug is not plugged into the rear remote VFO socket OR if the plug is not available, a wire jumper connected between pins 8 and 9 on the rear remote VFO socket, the VFO output will be "zero", the PLL Unit will switch to an "Unlock" state, the digital display will be dark/blank, and the 820 will NOT receiver and transmit.

41864. TV502/506 cables

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-23 20:31:10 UTC
From: Rick
Topic: 41864 Message: 41864

I have a TV-502 and a TV-506 I am hooking up to my TS-520. I have one cable with a plug on one end only. I have four (4) plugs ordered and on the way, but I am not sure of the wire I should use to make the jumpers. The cable I have (with the one plug on it) has a couple of small diameter coax cables in it along with different gauges of wire all inside the outer insulation of the cable. The manuals for both the TV-502 and TV-506 do not address the construction of this cable. My main concern is, do I need a special piece of 12 conductor cable using small diameter coax for a couple of the wires or can I simply use any 12 conductor cable? I assume #22 stranded wires within the cable would be sufficient in this case.

Thanks for any assistance,

Rick/K5IAR

Have you verified all the required oscillator frequencies are present at the PLL Unit?

Have you verified the VFO output frequency present at the PLL Unit? You can sample the VFO output frequency on the PLL unit board at PLL-1 pin 2 and ground on PLL-1 pin 1.

Have you also verified the CAR Unit signal is present at the PLL Unit? You can sample the CAR Unit signal at the PLL Unit plug PLL-1 Pin 6 and ground on pin 5.

All it takes is one missing signal or the signal is at a level that's unusable by the PLL Unit to cause the PLL to switch to a Unlock state.

Info...

Hybrid-Restore has these on their website, as well as on e-bay.
Mine came from there and is working well..

Alternative source is:
http://www.electronicsurplus.com/item/135797/
However there is a min order of $14 and ~S10 shipping.

Paul,

I have previously had similar issue with different slugs, I clean tip of soldering iron and then place on slug and gently heat up and turn immediately whilst still hot, works everytime so far!

Subject: [TS-520_820_530_830] Stuck Transmit Coil

With the help and advice from a previous thread, I was able to fashion one of my adjustment tools to turn all of the ANT and MIX coils fine (and perform the adjustment procedure for those).

I used a hard plastic chop stick and sand paper to fashion an adjustment tool for the larger slots in the transmit coils that works for all of them except 3.5MHz, which won't turn. I did the adjustment for all the others including T1 on RF and T10 on IF in conjunction with the 1.8MHz TX coil adjustment.

I dabbed that 3.5 TX coil top with a q-tip of WD-40 and let it sit for a day, still wouldn't turn, gave it another dab and another day... still won't turn.

It is not cracked or broken, just tight... tight enough that the very tip of the chop stick came off and is now resting in the little slot; I'll fish it out shortly...

I think it does need adjustment because 3.5MHz tunes up "differently" than all the other bands - LOAD control goes full clockwise without reaching RF peak. All the other bands peak LOAD in the center range.

Here is a tuneup snapshot of the bands to provide some data.
All /x figures are 12 hour clock face knob positions except Plate.

29.5MHZ 95W @ 210ma Load/11 Plate/28 Drive/2 Car/11:30
29MHz 105W @ 210ma Load/11 Plate/28 Drive/12 Car/1
28.5MHz 80W @ 210ma Load/11 Plate/28 Drive/11 Car/11
28MHz 80W @ 210ma Load/11 Plate/28 Drive/10 Car/11
21MHz 80W @ 210ma Load/12 Plate/21 Drive/12 Car/9:30
14MHz 80W @ 225ma Load/12 Plate/14 Drive/11 Car/10:30
7MHz 75W @ 225ma Load/11 Plate/(3.5!) Drive/10 Car/9
3.5MHz 65W @250ma Load/CW Plate/3.5 Drive/11 Car/10:30
1.8MHz 65W @250ma Load/1 Plate/18 Drive/11 Car/10

Is this stuck coil causing low power output on the lower bands around 3.5, as well?

Any ideas on how to free up this coil?
Something other than WD-40?
Application of heat?
Or spray it with cold?

Thanks,
Paul
AD5FT

Mike....Not sure how to check for oscillator freq'ys in the PLL unit....did manage to find and test vfo output and Car signals....not finding any action....did spend some more time going over things in regards to PLL operation and such....I have come a long way understanding these rigs......but alas still just an infant ....Thankyou for your input....

Wes,

I'm not sure what you mean by "not finding any action..." Are you saying you did not find the VFO and CAR signals at the PLL unit plugs I mentioned?

Jean,

The same plug that is used on the TS-515 (TS-511s) is used on the TS-510, it has pins 8 and 9 jumpered and pins 6 and 7 jumpered. The TS-510 and TS-515 only require pins 8 and 9 to be jumpered (pin 7 is unused), the additional jumper between pins 6 and 7 is required on the earlier JR-310. I have used the same plug interchangeably between my TS-510, TS-511s and JR-310. I hope this helps.

Regards,
Frank WX2FA

Many thanks Frank.

Yes I have this 9 pins plug I will give it a try while interconnecting pin8 and 9 of this connector.
Do you have any idee if I can use 6146B tubes in the final.
Are those last a good substitute,because I do not have finals yet for my TS510 !!

Regards and thanks Jean ON4AEF.

Thank you so much, Dave; that worked and I was able to proceed with the adjustment... but now I have another problem which I'm about to start another thread.

41877. Lost ALC during TX coil adjustment (TS-820S)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-24 13:44:20 UTC
From: paul.nussbaum
Topic: 41877 Message: 41877

I made an error during adjustment. Now ALC is gone.

At beginning the transmit coil adjustments (SG switch OFF, dummy load) I could not raise an ALC level on the meter, noticed the red LED light for the VFO was out, and digital display was out. I found the function switch set to CAL-RMT instead of VFO.

I don't remember turning it off of VFO, but there it was... I had just done the ANT and MIX coils using the CAL-25, so I must have made an error setting it back to CAL-RMT instead of VFO for the transmit coil adjustment.

I set it back to VFO and got the LED back on, digital display returned, but could not get any ALC on the meter when switching to Send to complete the transmit coil adjustments.

Now I don't get ALC in TUN.
Tune up in CW mode has extremely low output (couple of watts).
I have 60ma bias, HV is good.

Any suggestions where to look?

Thanks,
Paul

Paul,

I just got over that problem with my TS830. I would assume you either cleaned or replaced the RL1 relay on the audio board.

Also, take a good look at the power supply board and see if R14 is burned/charred. This is a 1k ohm 1 watt resistor in the screen grid supply line of abt 275 volts. I missed this resistor on my first inspection and beat my head in for days. Radio shack to the rescue.

I would also assume you have rf power.

Hope this helps, Keep me in the loop.

Love the hobby as I do,

73,

Mike/K3MG

Hi Young

Thanks for this confirmation about those tubes.
I can put some 6146B tubes in my Kenwood TS510 in place of old S2001A tubes

Regards es 73's Jean ON4AEF.

Hi,
It is the same as 6146B. Japanese copied exactly the same spec.

Hi Jean,
Yes, it would work fine. I found that the 6293 works as well.
The later production (after 1968) 6146W has a same spec. as the 6146B.
Good luck.

Grid current can still flow between the final tube cathodes and grids
even if the screen voltage is missing or significantly reduced.

The GRIDis positioned between the Cathode and the screen. If screen
voltage is lost (zeroVDC), electron flow will cease to the screens and
plate but that will not prevent grid current to flow between the cathode
and the grid. The grid is positioned between the cathode and the screen.
If the gridbecomes positive by the driver's RF signal level then current
will flow between the cathode and grid, even with zero screen voltage,
resulting in ALC being indicated on the ALC meter during TUNE mode
DRIVER adjustment. The IP meter indication will be zero because the
screen(screen voltage is zero) is "negative" in respects to the cathode
which blocks the flow of electrons to the screen and platebut that does
NOT prevent electrons from flowing to the positive grid (driver tubes
signal level pushes the grids "Positive").

To understand how this works you have to understand the "Electron Cloud" that hovers over the Cathode even when no conductionis occurring in the final tube (standby). This is all part of understanding how vacuum tubes work and how voltage, whether positive or negative, is applied each element in the tubeand what happens when these potentials change, either positive or negative. This is why it is very important to understand vacuum tube concepts in order to properly troubleshoot and service any vacuum tube circuit. You can easily "duplicate" the same indications by simply setting the rear SG switch to "OFF" (negative voltage is applied to the screens of the final tubes) then start the normal tranmitter tune up procedure in TUNE mode with the meter switch set to ALC, the Mode switch set to TUNE, and the SEND switch set to key the transmitter then adjust the DRIVE control and watch the ALC meter peak. Yes the ALC meter WILL show the "same" peak ALC indication with the SG switch set to OFF as it would with the SG switch set to ON. Don't believe it? Try it with your hybrid and you'll see!!

I forgot to mention, performing this "simple" test will NOT harm your Kenwood hybrid nor will it harm the final tubes!Performing simply test such as this is what those who want to learn should try. If you have any doubt at what I am telling you, try the simple test and you will seefor yourself that grid current (ALC indication) can and WILL occur even when the screen voltage is zero or has a negative voltage applied (SG switch in OFF position).

hi

I added a photo album Transverter Connectors,
shows the cables connected to the 12 pin Hirose plug.

There is a photo that shows the rca audio cable pigtail
I added to one cable so it will work with the TV-502.

Each cable is approx. 31" long connector end to end.
Four shielded cables are used and a few unshielded make
up the jacketed cable.

I have not cleaned or replaced the relay on the audio board, but I just observed its mechanical operation - the armature snaps to change position when the Send switch is activated in TUN mode.

I have inspected the boards generally with a flash light and magnifying glass and do not see any resistors that appear charred or burned.

The driver tube gets hot.
I have 60ma bias.
HV reads good.

In TUN mode, meter set to ALC, CAR up, Send switch on, I get no ALC peak with the Drive control anywhere in its range of rotation... the meter does not move from minimum. The meter does operate normally in Receive.

The loss of ALC began after switching to Send while the Function switch was erroneously set to CAL-Remote (with no remote VFO connected), with SG switched to OFF, into a dummy load... any idea what happens when one makes that mistake?

I need a methodology to know what and where to look and measure to find out what has changed to cause the missing ALC.

In the mean time, I'm looking at the schematics, board pictures, and other material to see if I can understand where the ALC is supposed to be...

Thanks,
Paul

Topic: 41362 Message: 41889

Here's an update and happy ending.
There was a fault with a relay which was rectified but also I'm following a different tune up procedure and there has been no recurrence of the "fault"

I only adjust the drive control for max noise while in recv, then go to tune, dip the plate, adjust rf using load control, the set alc with carrier control .

I have not encountered any recurrence of the problem I was having. This tune up method is a variation of the ones I've seen demonstrated on you tube, the user manual and other published tune up process where the drive control is used to adjust alc level.

Im going with what has worked for me an start to enjoy using this grand old radio. It made a debut on the boat anchor net with good reports and bottle shop net is next to make an entrance on (VK 80m nets)

Improving antenna for 40/80 is next on the list but I also have a craving for a project radio -520s or similar to work through.

Does this mean I'm hooked?
Is there a known cure?

Topic: 41890 Message: 41890

I've had no luck obtaining a working replacement board, nor finding one for parts use:(

The PO of this rig must have "screw-drivered" the IF cans.
Cores are broken in all sections, Ant, Mix, Drv.

It looks like the TS-820 has the same cores/cans on the DRV side, so I'm going to look for a donor board for those.

I'm going to need at least 8 new cores for the ANT, Mix side and possibly a couple of cans (160,80,40,30,20M)

Anyone know a source for cores/cans? Bob M is currently out of the RF units (working or not)

Topic: 41890 Message: 41891

I have had some success with using a small screwdriver and a drop of superglue to extract broken cores from coils - although I have yet to try this with a TS-820 or 520, I have a couple that could use it.

It appears to me that the best source for such cores is old CB radios or consumer electronics that use similar sized coils. They sure look similar and I have acquired a few for that purpose. Well, actually I acquired some over the last 30 years for various purposes. Try some flea markets or maybe even E-bay.

All Electronics has some IF transformers at 3 for $1.00 that might provide a source as well, although I can't tell from just looking a the picture they supply.

And, of course, never pass up an interesting looking trash pile!

Good luck!

Robert

Paul,

Your reference to 60ma being "bias" is wrong! None of the meter switch settings will show you biaswith the transmitter keyed. The IP meter's displaying 60ma,with the transmitter keyed, is showing you the Class AB1 final tube's "idling current" flowing in the final tubes, NOT biasor bias voltage!

Mike

If you peak the Drive control with Rx background noise or the marker signal can you then load the rig into dummy load and get approx 100 watts out? Do you have an external wattmeter? If not, suggest you get one. They are not only a good loading aid, but a piece of test gear. Can tell you much more than HV and IP meter in cases like this or when you have an open or shorted coax situation.

If you can load into dummy load then you have RF drive being produced and you have an ALC indication problem or your alignment is such that you do not have enough RF drive at the 6146 control grids to overcome the operating negative DC bias voltage on positive peaks of the RF drive envelope and cause a small level of grid current to flow. A small level of 6146 grid current (approx 40 ua) is required for ALC indication.

It is possible to have pretty decent RF output without having any ALC indication.

Here is some background:

A small amount of grid current (micro-amperes)is required to turn on the ALC amp and pull down the ALC bus voltage which will cause the ALC meter to move up scale. The ALC meter is a FET based voltmeter that measures the ALC bus line voltage. With ALC bus at 3.3vdc the meter will rest at zero on the scale. As microampere grid current flows from RF drive overcoming final control grid dc bias voltage the ALC amp will be turned on and will pull down the ALC bus which is a high Z source and cant stand any load on it. The ALC amp acts like a variable load resistor controlled by grid current produced on positive peaks of the RF drive envelope.

Need to make some measurements.
1. With SG switch off and rig in CW mode peak the Drive control on Rx back ground noise or the marker signal. Then flip to send and measure the RF drive level voltage at Pin 5 of the 6146 control grids. You need a RF millivolt meter, O-scope, or multi-diode rf probe/vtvm to measure this rf voltage. You should have approx 47 rms volts.

2. Measure the negative dc operating bias voltage on Pin 5 with rig keyed. It should be approx -55vdc.

3. Measure RF-1 ALC reference voltage at AF/AVR board. It should be approx 3.3vdc. If not set it with VR-1 trim pot.

Now with your result do a little math.

1. Assume you have 39rf volts then 39 x 1.414 = 55 peak rf volts
2. Assume you have -58vdc grid bias.
3. Then you are approx 3 volts short of grid being 0 volts on peak of the rf drive envelope. Will have no grid current, no ALC amp turn on, no ALC bus voltage pull down, no ALC meter movement up scale.
4. With -58 vdc bias you will need a minimum of approx 41 rf volts. 41 x 1.414 = 57.9 peak rf volts. At 41 rf volts drive the control grid will be 0 volts on peak of the rf drive envelope and just at point of starting to see grid current.

5. So with -58vdc grid bias you will need more than 41 rms rf volts drive to get ALC indication.
6. Set the bias voltage for 60ma resting plate current and then measure that voltage level to see if it is close to -55vdc.
7.With bias voltage set to -55vdc you will need 55/1.414 = 39 rms rf volts drive to get to 0. So 39 rf volts is minimum rf drive you need.

The way you get required 39 plus Rf drive voltage level is by having a good Driver tube, spec Driver tube DC voltages (screen is especially important),spec 6146 control grid dc bias voltage, and good Mixer and Drive coil alignment. Since you apparently had good ALC indication at one point in the coil pack alignment procedure I do not suspect bad high resistance bandswitch contacts.

Sorry so long. Only way I know to quickly and efficiently troubleshoot is to run portion of TX Level Diagram that you will find in the Service manual. Once you know where RF drive voltage is low or missing can focus troubleshooting efforts at that stage/component. It bemuses me why so few folks understand or use TX Level Diagrams.

Date: 2013-04-25 07:36:17 UTC
From: paul.nussbaum
Topic: 41877 Message: 41895

Thanks Terry,

I am using the dummy load in a Dentron antenna tuner that includes forward and backwards watt meters. When I load in CW mode I get just a couple of watts output on the external meter, nothing on the TS820S meter set to RF.

Thanks for the overview of ALC function.

Measurements

RF drive level voltage at Pin 5 of the 6146 control grids...
I don't have proper instruments, only a VOM. I'll look at some VTVMs tomorrow at the electronics shop... any recommendations?

Pin 5 of the 6146 grid #1:
Finals circuit diagram specs (-100V/-55V)
I measure both tubes at
-99.5V before transmit
-57.5V during transmit
.
ACL ref voltage spec (3.3V), I measure 3.28V

12BY7A Pin 2 grid #1
RF board circuit diagram specs (-43V/0V)
I measure
-40.2V before transmit
.003V during transmit

12BY7A Pin 8 Grid #2 (screen)
RF board circuit diagram specs (250V/210V)
I measure
255V before transmit
224V during transmit

So,
I need the measurement of the RF drive level voltage at Pin 5 of the 6146 control grids to proceed with calculations, but it looks like 6146 control grid DC bias voltage, ALC reference voltage, 12BY7A Grid 1, and 12BY7A Grid 2 (screen) are close to spec... ?

Mix and Drive coils may be close, but I'll repeat after getting the ALC figured out.

In the mean time I'm looking at the TX level diagram...
Paul

(TS-820S)

If you peak the Drive control with Rx background noise or the marker signal can you then load the rig into dummy load and get approx 100 watts out? Do you have an external wattmeter? If not, suggest you get one. They are not only a good loading aid, but a piece of test gear. Can tell you much more than HV and IP meter in cases like this or when you have an open or shorted coax situation.

If you can load into dummy load then you have RF drive being produced and you have an ALC indication problem or your alignment is such that you do not have enough RF drive at the 6146 control grids to overcome the operating negative DC bias voltage on positive peaks of the RF drive envelope and cause a small level of grid current to flow. A small level of 6146 grid current (approx 40 ua) is required for ALC indication.

It is possible to have pretty decent RF output without having any ALC indication.

Here is some background:

A small amount of grid current (micro-amperes)is required to turn on the ALC amp and pull down the ALC bus voltage which will cause the ALC meter to move up scale. The ALC meter is a FET based voltmeter that measures the ALC bus line voltage. With ALC bus at 3.3vdc the meter will rest at zero on the scale. As microampere grid current flows from RF drive overcoming final control grid dc bias voltage the ALC amp will be turned on and will pull down the ALC bus which is a high Z source and cant stand any load on it. The ALC amp acts like a variable load resistor controlled by grid current produced on positive peaks of the RF drive envelope.

Need to make some measurements.
1. With SG switch off and rig in CW mode peak the Drive control on Rx back

ground noise or the marker signal. Then flip to send and measure the RF drive level voltage at Pin 5 of the 6146 control grids. You need a RF millivolt meter, O-scope, or multi-diode rf probe/vtvm to measure this rf voltage. You should have approx 47 rms volts.

2. Measure the negative dc operating bias voltage on Pin 5 with rig keyed. It should be approx -55vdc.

3. Measure RF-1 ALC reference voltage at AF/AVR board. It should be approx 3.3vdc. If not set it with VR-1 trim pot.

Now with your result do a little math.

1. Assume you have 39rf volts then 39 x 1.414 = 55 peak rf volts
2. Assume you have -58vdc grid bias.
3. Then you are approx 3 volts short of grid being 0 volts on peak of the rf drive envelope. Will have no grid current, no ALC amp turn on, no ALC bus voltage pull down, no ALC meter movement up scale.
4. With -58 vdc bias you will need a minimum of approx 41 rf volts. 41 x 1.414 = 57.9 peak rf volts. At 41 rf volts drive the control grid will be 0 volts on peak of the rf drive envelope and just at point of starting to see grid current.
5. So with -58vdc grid bias you will need more than 41 rms rf volts drive to get ALC indication.
6. Set the bias voltage for 60ma resting plate current and then measure that voltage level to see if it is close to -55vdc.

From: Terry Wagoner
Topic: 41877 Message: 41897

Paul: Couple of things. Good job on getting the DC voltages. VOMs typically have 50,000 ohms/volt sensitivity so OK for plate and screen voltages but not good for ALC or AGC bus and getting on grids of vacuum tubes.

1. Suggest you get a DMM or a VTVM to get higher input impedance. I prefer the old Heath VTVMs like a IM-18 as it has 11 meg input Z and wont load down your readings and a large analog scale to see peaks and nulls. I suggest Heath as they made 10s of thousands so can always buy a spare for a parts unit. A good DMM also has its place for the DC readings that you just took. Most will have a 10 meg Z, but some do not. A cheap Harbor Freight measures at just under 1 meg and some have different Z depending on the meter range.

2. I assume you have the Tuner in Bypass? Tuner watt meter is fine.

3. I assume you have advanced CAR Level Pot full CCW and peaked the Drive Control. It may not peak at 1200.

4. Your DC readings look good. You can see that you have proper switch over from cutoff to operating bias voltage on the Driver Tube and the Finals.

5. I assume that your -57.5 vdc bias voltage is with 60 ma resting plate current. At -57.5 you will need -57.5/1.414 = 40.67 rms rf volts drive at 6146 Pin 5. So anything less than approx 41 rf volts drive and you will have no ALC meter indication. Anything greater than 41 rf volts and you should see ALC indication assuming the ALC metering is working. Suggest you follow previous suggestion to clean aux relay contacts. Good idea to clean them as easy to do and AGC and ALC bus line is switched by this relay.

6.With the lower RF output you could use a single germanium diode RF probe to take the TX Level diagram readings to see where losing it at. Normally suggest use a two or three diode probe to get on plate of 12BY7A or grid of 6146 finals so you do not exceed the peak inverse voltage of the single diode. See N5ESE to make a probe or buy Hendricks kit or buy used Heathkit 309-c etc off ebay.

7. You cannot accurately measure TIF signal from IF board using RF probe as it is too low a level (approx 35 mv). Absent RF millivolt meter use an O-scope to measure TIF. If you have good RF level at output of TX Mixer safe to assume have adequate TIF level.

Took covers off my TS-820 this AM and here are my readings which may help you. I took these after loading rig at 14.2 mhz into dummy load to 100 watts output. I then turned off SG switch.

1. Cutoff bias voltage on 6146 Pin 5 = -95.10vdc
2. Operating bias voltage on 6146 Pin 5 = -50.25 @60ma resting Ip
3. RF voltage at Pin 5 = 42.2 rf volts
4. CAR Level Pot at number "2"
5. ALC indication at full scale deflection (FSD)and holding there.

So my delta is 42.2 x 1.414 = 59.67 peak rf volts. 59.67 - 50.25 = 9.42 volts.

You can see I am swinging the control grids approx 9 volt positive on peaks of rf drive envelope which results in microampere grid current flowing and ALC meter driving to full scale deflection.

Rob:

Yes I like to go to my white board or sheet of paper and draw the ALC circuit and figure out how it works. Can then take some measurements when working per design and record for future when it doesnt. I try to do that with all the circuits as the circuit descriptions all could use further development. Kenwood gave just enough detail for casual user on the main functional blocks.

ALC in the Hybrids is derived differently than most rigs that sample and rectify some rf output to develop the control voltage. With the hybrids the control voltage is always there derived from AVR board RF-1. We pull it down when grid current just begins to flow. Kenwood calls it Amplified ALC which is kind of a misnomer as the ALC transistor is not amplifying a signal it is acting like a variable resistor. I have a nice HP-410C 100 meg Z VTVM which I can actually watch ALC voltage pull down from RF-1 level as we increase RF drive. You can measure with a VTVM but it will pull down the voltage to around 2.6 to 2.7 vdc when you connect it and drives the S-meter upscale to around S3 to S4.

You are not actually looking directly at Grid current when you peak the Drive control. Kenwood has no grid current meter shunts or grid current meter position. This isnt necessary for Class AB1 as there is no grid current. The grid requires no driving power only rf voltage swing. The moment that the driving envelope exceeds the dc operating bias offset and grid current begins to flow ALC bus line voltage is pulled down and TIF rf drive level is reduced. The cow just barely makes it out of the barn before it is pulled back!

It is impossible to over drive the control grids of the finals and exceed the max grid dissipation.

I think all the people who load by making sure the ALC is in middle of the black box or no more than the top of the black box ALC range are confusing it with another design or just dont understand how it works. On You Tube you can see some precautions about this presented by Extra Class holders. They have you peak in the black box and go back and check when done and adjust Car pot again. None of which is in the operating manual loading instructions. I guess they have good intentions. With a science or technical hobby need more than good intentions. Thankfully they are doing no harm to the rig. I have tried to explain this too more than one of these fellows, but most are stubborn and continue to load as they understand how the radio works. Fortunately no harm done unless drive is marginal to begin with.

Some old timers may do this as we were all taught not to exceed max 6146 grid current of approx 2.5 ma to 3.0 ma on our 1950/1960 vintage 50 watt CW Class C Grid Leak Bias transmitters. We had to go back after loading into our lite bulbs and check and adjust grid current reading level. Never wanted to exceed grid current or have loss of grid drive with grid leak bias rigs.

None of that applies to a Hybrid. Its operating bias is fixed bias and not grid leak developed. Of course Kenwood could have been clearer on what they meant when the manual tells you to peak Drive control to maximum ALC indication. Almost every new owner asks

immediately if that means max of black ALC box range or max on the meter scale. Just give a decent CAR Level so you can see a good peak as you tune the Drive stage to resonance. 2/3 to 3/4 scale is good place, but max on ALC box works just fine as well.

The black ALC box is meaningless while loading the rig. It is there for SSB mode to ensure linear operation. When you talk up to the max of the black box you have approx 40ua to 45ua of grid current. Kenwood actually varies the ALC time constants to use it as a crude means of speech compression to increase your talk power without introducing too much adjacent frequency splatter. In no case should you talk rig up outside the ALC box. I try to keep it no more than mid-range. Technically when you have no indication you are operating at most linear place.

I do not have a spectrum analyzer, but have asked the fellows who have L-pans and K3 rigs or similar to look at my signal while I varied the Mic gain for various ALC indications and no one sees any trash if I talk up to the max of the black box.

Probably much more than you wanted.

Rob:

Appreciate your feedback. Not looking for any recognition. Guys like me and Mike and others of our generation are just trying to pass on what we learned over 50 years as we are concerned about who will hold up the Tent Poles when we are gone. With the hobby feeder system radically altered and interest level drying up I think I can speak for Mike when I say we hate to see Hybrids end up on the junk pile or collectors shelf because no one has the basic fundamental radio theory knowledge that they can apply to understanding how these treasures work and how to operate and maintain them.

Look for a TS-530 service manual. They are available on-line.
Then goto page 9 I believe, it has the instructions and illustration.

41906. How to Measure 6146 Grid Current

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-25 14:35:48 UTC
From: Terry Wagoner
Topic: 41906 Message: 41906

Hopefully last post from me for today. Fingers worn out !

Got off list email questioning how I measured grid current. This person has always loaded by varying CAR pot to make sure ALC stays in black box range. He is skeptical that grid current is as low as 40ua (microamperes). I directed him to Ken Kempski site where he discusses nano-ampere grid current.

I take no offense and dont see this as a challenge. I expect everyone to evaluate and validate what I post here. I make mistakes daily.

Just a reminder of what Grid current is. When the control grid is positive with respect to the cathode dc current will flow from the cathode to the grid and return back to ground thru the -C supply. To measure it we can break the FG lead at the Finals board and get a meter in series. Just make sure you lift at the FG lead and insert meter so that RF choke is still in the path preventing any RF from going back to ALC amp and -C supply. There is an easier way that does not require lifting FG lead.

Here are several ways to measure grid current.
1. Lift the FG lead and insert a 50ua meter movement in series. Be careful with test leads as dealing with -100 vdc.

2. Lift the FG lead and insert a Multi-meter that has DC ua ranges on it. A milli-ohm meter is good for this, but hams seldom have as expensive. I have a very nice Simpson 2795 FET meter that has ua ranges down to 1ua full scale and I have used the 100ua range. This meter has these low ranges as it was used to troubleshoot cathodic protection among other low current circuits. See them from time to time on Ebay. With any multimeter that you put in series with the FG lead and Final board to read dc current level you need to read your manual and look at the Burden Voltage. Some of newer DMMs have very poor Burden. It can greatly affect the accuracy of dc current readings. If you dont understand Burden suggest you Google on it.

3. A method that most hams can employ is the IR drop method that requires no lifting of the FG lead. All the hybrids have a series resistor in the FG line and ALC amp transistor emitter lead. It is typically a 10k resistor and makes an ideal place to read the IR drop and calculate the grid current. I know this aint direct reading but neither is your Ip reading.

Here is how I do it on the TS-830 and it works equally well on the other rigs.

A. Use two micro-grabber test leads. Connect one grabber lead to the FG terminal and connect the other lead to the Emitter of Q19 on the Audio Board. Be careful not to short Q19 leads when connecting to the emitter lead. You will now have your test leads across 10K resistor R102.

B. Load rig to 100 watts out in CW mode and flip SG switch off.

C. Connect your DMM across the micro grabber test leads.

D. Flip to send and measure the voltage drop across R102. You should read approx 0.40 vdc. Try varying your Car pot and watching the voltage drop ie current.

E. I = E/R (darned old theory again) I = 0.40/10,000 = .000040 or 40 ua.

Here is sample of TS-830 6146 Grid current for varying Car pot levels, varying RF drive levels, and varying levels of indicated ALC on the panel meter.

Freq = 7.2 mhz
RF drive = 47.5 volts
Grid Current = 41.5ua
Car pot = 1.5
Meter ALC indication = 50% of black box

RF drive = 48.0 volts
Grid current = 43.7 ua
Car pot = 2.0
Meter ALC indication = 100% of black box

RF drive = 48.0 volts
Grid current = 45.2 ua
Car Pot = 6.0
Meter ALC indication = FSD (just off the peg)

So you can see it doesnt matter where you peak the AlC indication at. You will have a maximum of 41ua to 45ua of 6146 control grid current with ALC meter indicating in the ALC black box and at FSD. Just no way to approach or exceed the 4 ma grid current max for ICAS service. Not a concern with Kenwood hybrids.

OK enough for today.

I agree with Terry, we're not looking for the "proverbial" pat on the back. We're also not a couple of old farts, hiding in the shadows, complaining like Jeff Dunham's "Walter" character, but rather we're hams who believe the importance of having a solid basic knowledge base and an understanding of how the hybrids work, before any attempt to operate, troubleshoot and repair any hybrid transceiver.

There isn't a "Geek Squad" you can call on the telephone and have them come to your house to show you how to operate your hybrid, that's what the operator's manual is for. I would never dream of attempting to operate a transceiver such as a Kenwood hybrid without taking the time to read and understand the operating instruction. If I had trouble understanding what the manual is telling me, I would come here and ask for help/explanation. This doesn't happen that often here and that's a shame. A Kenwood hybrid is NOT a television set or a surround sound amplifier where you don't need to understand electronics to operate it. All you have to do with TVs and surround sound systems today is plug it in, connect it to the sat box, cable source, put the batteries in the remote, connect a few speakers, then press the RED ON/OFF button. The Kenwood hybrids are advanced transceivers where the operator should take the time to study the operator's manual before operating the transceiver. A lot of hybrids are bought on ebay, hamfest, and/or from private sales. If the manual doesn't come with the transceiver at the time you buy it, get it and study it BEFORE any attempt is made to operate the transceiver.

Yes, we do get frustrated at times. We don't expect everyone to be experts but we do believe that it's important for the ham who wants to operate their hybrid's properly and learn how to service their hybrid, should at least do "their part" and study. One can't learn and fix anything if they rely solely on someone else to do all the research and give them ALL the answers.

Kadambari,

I hope you enjoy the book - obviously not a long treatise on the subject, but a useful (I hope) deskbook.

The return flight was long (10 hours) but uneventful - the best sort of flight!

Kenwood gave just enough detail for casual user on the main functional blocks.
>
>ALC in the Hybrids is derived differently than most rigs that sample and rectify some rf output to develop the control voltage. With the hybrids the control voltage is always there derived from AVR board RF-1. We pull it down when grid current just begins to flow. Kenwood calls it Amplified ALC which is kind of a misnomer as the ALC transistor is not amplifying a signal it is acting like a variable resistor. I have a nice HP-410C 100 meg Z VTVM which I can actually watch ALC voltage pull down from RF-1 level as we increase RF drive. You can measure with a VTVM but it will pull down the voltage to around 2.6 to 2.7 vdc when you connect it and drives the S-meter upscale to around S3 to S4.

>
>You are not actually looking directly at Grid current when you peak the Drive control. Kenwood has no grid current meter shunts or grid current meter position. This isnt necessary for Class AB1 as there is no grid current. The grid requires no driving power only rf voltage swing. The moment that the driving envelope exceeds the dc operating bias offset and grid current begins to flow ALC bus line voltage is pulled down and TIF rf drive level is reduced. The cow just barely makes it out of the barn before it is pulled back!
>
>It is impossible to over drive the control grids of the finals and exceed the max grid dissipation.

Thank you, Terry.

I appreciate your help learning about this. Addressing your points:

1] Thanks, I'll be looking today for a proper meter., but see 6 and 7 below...

2] Yes, tuner bypassed, straight to dummy load

3] Yes, using marker, CAR CCW

4] Good; is it the relay on the AF board that switchs over from cutoff to operating bias?

5] Hmm... I'm not clear on this... I made all the DC readings in CW mode. I can see 60ma on the meter selected to Ip when mode is SSB during Send on. I measured -57.5V during Send on in CW mode; but I'm used to observing in CW mode that the Ip with the Send on is 75ma before closing the key. Did I measure -57.5V with 75ma resting plate current? Do I need to use SSB mode to measure the bias voltage with 60ma?

6] and 7] I'm not clear on the differences between DMM, VTVM, RF probe, and RF millivolt meter... looking around the internet I see RF probes (and probe circuits) associated with both DMM and VTVM, and I see millivolt meters that can't be used for RF measures. I don't have an o-scope.

I'm heading to the electronics shop shortly to see what I find there...

Thanks much,
Paul

>
> Paul: Couple of things. Good job on getting the DC voltages. VOMs typically have 50,000 ohms/volt sensitivity so OK for plate and screen voltages but not good for ALC or AGC bus and getting on grids of vacuum tubes.
>
> 1. Suggest you get a DMM or a VTVM to get higher input impedance. I prefer the old Heath VTVMs like a IM-18 as it has 11 meg input Z and wont load down your readings and a large analog scale to see peaks and nulls. I suggest Heath as they made 10s of thousands so can always buy a spare for a parts unit. A good DMM also has its place for the DC readings that you just took. Most will have a 10 meg Z, but some do not. A cheap Harbor Freight measures at just under 1 meg and some have different Z depending on the meter range.
>
> 2. I assume you have the Tuner in Bypass? Tuner watt meter is fine.
>
> 3. I assume you have advanced CAR Level Pot full CCW and peaked the Drive Control. It may not peak at 1200.
>

> 4. Your DC readings look good. You can see that you have proper switch over from cutoff to operating bias voltage on the Driver Tube and the Finals.
>
> 5. I assume that your -57.5 vdc bias voltage is with 60 ma resting plate current. At -57.5 you will need -57.5/1.414 = 40.67 rms rf volts drive at 6146 Pin 5. So anything less than approx 41 rf volts drive and you will have no ALC meter indication. Anything greater than 41 rf volts and you should see ALC indication assuming the ALC metering is working. Suggest you follow previous suggestion to clean aux relay contacts. Good idea to clean them as easy to do and AGC and ALC bus line is switched by this relay.
>
> 6.With the lower RF output you could use a single germanium diode RF probe to take the TX Level diagram readings to see where losing it at. Normally suggest use a two or three diode probe to get on plate of 12BY7A or grid of 6146 finals so you do not exceed the peak inverse voltage of the single diode. See N5ESE to make a probe or buy Hendricks kit or buy used Heathkit 309-c etc off ebay.
>
> 7. You cannot accurately measure TIF signal from IF board using RF probe as it is too low a level (approx 35 mv). Absent RF millivolt meter use an O-scope to measure TIF. If you have good RF level at output of TX Mixer safe to assume have adequate TIF level.

I spent most of my ham career with no RF Wattmeter hooked up.
Most of the rigs I used had a final tube plate current meter that we used to peak drive and dip plate current and set loading capacitor to a specified Ip at plate tuning dip,
 This was a given, that those settings would give you max RF output within final tube specs, and that worked just fine !

If you peak the Drive control with Rx background noise or the marker signal can you then load the rig into dummy load and get approx 100 watts out? Do you have an external wattmeter? If not, suggest you get one. They are not only a good loading aid, but a piece of test gear. Can tell you much more than HV and IP meter in cases like this or when you have an open or shorted coax situation.
It is possible to have pretty decent RF output without having any ALC indication.

Do you need just the slugs except for the one you say you need the Coil
as well or are you after the complete coil with slug installed ?
Dollar Value for all ?
I have the 80 meter Ant slug, but not a complete Coil for 80 Ant.

To understand how this works you have to understand the "Electron Cloud"
that hovers over the Cathode even when no conductionis occurring in the
final tube (standby). This is all part of understanding how vacuum tubes
work and how voltage, whether positive or negative, is applied each
element in the tubeand what happens when these potentials change, either
positive or negative. This is why it is very important to understand
vacuum tube concepts in order to properly troubleshoot and service any
vacuum tube circuit.

I suppose you measure voltage with your finger tips as well. I would not be surprised. A watt meter is a tool just like a voltmeter. I dont consider it a frill or luxury.

The old dip and load method certainly works to load a hybrid, but tuning to max rf output without exceeding max Ip is easier to do, quicker to do, less stress on the finals, easier to teach, and most efficient place to operate at. Before wattmeters we all used lamp bulbs on are tuned feeders or thermocouple RF ammeters to load are rigs. I dont think very many were limited to just a plate current meter and if you were you soon learned the limitations of it. I think the last time I was limited to just dip and load was with my DX-20 in 1960.

Even Kenwood was smarter than that as they gave us the RF meter position so we at least had relative RF power indication to load with.

Also the dip is not necessarily where you want to operate. Depending on several factors including neutralization the dip may or may not occur at maximum RF output. I think you need to read about over-coupling and under-coupling which my Elmer taught me back in the 50s/60s AM transmitter and amplifier days.

Even Kenwood came around to realizing that no need to use Dip and Load method. Read the TS-530 and TS-830 loading instructions. On the TS830 go to page 18 and read the very last NOTE. It is pretty clear what they think is a simpler method.

Lastly unscrew your coax connector off your hybrid and load using the Dip and Load method and tell me what you see. I wonder if a new hybrid owner today would recognize it?

Since you need an SWR bridge to trim your antennas it is silliness not to invest just a few dollars more in a Wattmeter that serves 3 functions
1. Tuning and modulation aid (it will have much better ballistics than your Ip meter for determining mic gain settings)
2. Troubleshooting your feed line and antenna and showing intermitants and faults easier than your Ip or HV meter.
3. Use to measure SWR

A Heath HM-102 can be had for $50 and a Drake W4 for around $70. I am not telling the new folks they must have a peak reading Bird.

A wattmeter is just another nice tool to have at the operating position and in the shack. Ip X Hv = DC input power, which may or may not have any direct relationship to output power.

I think new folks who follow my advice will appreciate what this tool will do for them.

>Yes I like to go to my white board or sheet of paper and draw the ALC circuit and figure out how it works. Can then take some measurements when working per design and record for future when it doesnt. I try to do that with all the circuits as the circuit descriptions all could use further development. Kenwood gave just enough detail for casual user on the main functional blocks.
>
>ALC in the Hybrids is derived differently than most rigs that sample and rectify some rf output to develop the control voltage. With the hybrids the control voltage is always there derived from AVR board RF-1. We pull it down when grid current just begins to flow. Kenwood calls it Amplified ALC which is kind of a misnomer as the ALC transistor is not amplifying a signal it is acting like a variable resistor. I have a nice HP-410C 100 meg Z VTVM which I can actually watch ALC voltage pull down from RF-1 level as we increase RF drive. You can measure with a VTVM but it will pull down the voltage to around 2.6 to 2.7 vdc when you connect it and drives the S-meter upscale to around S3 to S4.
>
>You are not actually looking directly at Grid current when you peak the Drive control. Kenwood has no grid current meter shunts or grid current meter position. This isnt

necessary for Class AB1 as there is no grid current. The grid requires no driving power only rf voltage swing. The moment that the driving envelope exceeds the dc operating bias offset and grid current begins to flow ALC bus line voltage is pulled down and TIF rf drive level is reduced. The cow just barely makes it out of the barn before it is pulled back!
>
>It is impossible to over drive the control grids of the finals and exceed the max grid dissipation.
>
>I think all the people who load by making sure the ALC is in middle of the black box or no more than the top of the black box ALC range are confusing it with another design or just dont understand how it works. On You Tube you can see some precautions about this presented by Extra Class holders. They have you peak in the black box and go back and check when done and adjust Car pot again. None of which is in the operating manual loading instructions. I guess they have good intentions. With a science or technical hobby need more than good intentions. Thankfully they are doing no harm to the rig. I have tried to explain this too more than one of these fellows, but most are stubborn and continue to load as they understand how the radio works. Fortunately no harm done unless drive is marginal to begin with.
>
>Some old timers may do this as we were all taught not to exceed max 6146 grid current of approx 2.5 ma to 3.0 ma on our 1950/1960 vintage 50 watt CW Class C Grid Leak Bias transmitters. We had to go back after loading into our lite bulbs and check and adjust grid current reading level. Never wanted to exceed grid current or have loss of grid drive with grid leak bias rigs.
>
>None of that applies to a Hybrid. Its operating bias is fixed bias and not grid leak developed. Of course Kenwood could have been clearer on what they meant when the manual tells you to peak Drive control to maximum ALC indication. Almost every new owner asks immediately if that means max of black ALC box range or max on the meter scale. Just give a decent CAR Level so you can see a good peak as you tune the Drive stage to resonance. 2/3 to 3/4 scale is good place, but max on ALC box works just fine as well.
>
>The black ALC box is meaningless while loading the rig. It is there for SSB mode to ensure linear operation. When you talk up to the max of the black box you have approx 40ua to 45ua of grid current. Kenwood actually varies the ALC time constants to use it as a crude means of speech compression to increase your talk power without introducing too much adjacent frequency splatter. In no case should you talk rig up outside the ALC box. I try to keep it no more than mid-range. Technically when you have no indication you are operating at most linear place.
>
>I do not have a spectrum analyzer, but have asked the fellows who have L-pans and K3 rigs or similar to look at my signal while I varied the Mic gain for various ALC indications and no one sees any trash if I talk up to the max of the black box.

41917. Re: Lost ALC during TX coil adjustment (TS-820S)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-25 20:23:31 UTC
From: Terry Wagoner
Topic: 41877 Message: 41917

I never said load for max out regardless of Ip. Do not know where you got that from. I have always taught and observed after adjusting the tank capacitor to resonance in Tune mode ie dipping the plate current then load for max out without exceeding the max plate current for your particular transmitter. Leave meter on Ip position and use wattmeter to load for max output.

There are numerous ways you can get 200ma or 225ma on the Ip meter position and not have 100 watts output.

A new person may have no clue as to what a LC parallel resonant circuit is, what a Pi-network is, what the Tank capacitor or the loading capacitor do. When they have problems inside that PA cage or with whatever is connected to that SO-239 connector it is nice to have a wattmeter to tell them they have a problem.

My comments included you too Mike 8-)

When I was typing the first post I was going to include all of the names of the people that I keep seeing post, even a couple from VK but I decided against it just in case I forgot someone.

I believe that this and most other Amateur related groups displays some of the true spirit of Amateur Radio, that is to impart knowledge and to " fix it yourself "

Terry added a third point, one that I hadn't considered, to carry on the Torch for these great radios for years to come.

Just occasionally it's nice to recognize the unselfish efforts of others 8-)

Cheers Mike and Group,

73's

Rob. VK3BRS

I agree with Terry, we're not looking for the "proverbial" pat on the back. We're also not a couple of old farts, hiding in the shadows, complaining like Jeff Dunham's "Walter" character, but rather we're hams who believe the importance of having a solid basic knowledge base and an understanding of how the hybrids work, before any attempt to operate, troubleshoot and repair any hybrid transceiver.

There isn't a "Geek Squad" you can call on the telephone and have them come to your house to show you how to operate your hybrid, that's what the operator's manual is for. I would never dream of attempting to operate a transceiver such as a Kenwood hybrid without taking the time to read and understand the operating instruction. If I had trouble understanding what the manual is telling me, I would come here and ask for help/explanation. This doesn't happen that often here and that's a shame. A Kenwood hybrid is NOT a television set or a surround sound amplifier where you don't need to understand electronics to operate it. All you have to do with TVs and surround sound systems today is plug it

in, connect it to the sat box, cable source, put the batteries in the remote, connect a few speakers, then press the RED ON/OFF button. The Kenwood hybrids are advanced transceivers where the operator should take the time to study the operator's manual before operating the transceiver. A lot of hybrids are bought on ebay, hamfest, and/or from private sales. If the manual doesn't come with the transceiver at the time you buy it, get it and study it BEFORE any attempt is made to operate the transceiver.

Yes, we do get frustrated at times. We don't expect everyone to be experts but we do believe that it's important for the ham who wants to operate their hybrid's properly and learn how to service their hybrid, should at least do "their part" and study. One can't learn and fix anything if they rely solely on someone else to do all the research and give them ALL the answers.

41921. "Angel hair" for rewinding L41....

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Well,

My #42 came in...good thing it is a 1600ft spool...LOL (smallest I could find).

If you need some, let me know.

Boy oh boy...it is "Angel hair" and with my fat fingers.....:)

On the serious side, what if the windings overlap or cross, does it make a difference?

Thanks to everyone here for the help and suggestions.
By shear luck I ran across a fellow ham whom had some spares.

This will save a ton of work, as my RF unit was in very sad shape.

Ditto on the relay (Ant relay), just replaced it on my TS-830, it's the same relay/location as on the 530 I believe.
Fixed the rx issue...
If you cannot find it in the UK, Jim at www.Hybridrestore.com has them.

Topic: 26 Message: 41925

You are all talking about very different relays. K0ZL is talking about the 4PDT flat pack aux relay which does cause several intermittent problems. Ordinarily I would advise you to troubleshoot this condition by studying the RX path from the SO-239 to the RF board and first exhausting the experiential based items followed by signal injection/signal tracing and not just replacing a relay on a guess. I have seen poor solder connection at the So-239 where tinned lead will actually pull out, dirty RF attenuator switch, dirty RF board molex Conn 3, or bad solder connection at Conn 3.

The antenna T/R relays for the TS-530 and the TS-830 are different animals. Both are located under the PA cage in metal shield cans. The TS-830 uses a plug in Omron MX-2P and the the TS-530 uses a miniature solder in Fujitsu FBR321DO12. It is Kenwood part number S51-2407-05 and no longer available. Also, the two antenna T/R relays will not interchange. I have never seen a MX-2P in a TS-530, but have heard of at least one owner who reports one installed which I believe is a mod unless it is an export version of the 530. You need to determine which configuration you have and easy to do by pulling the shield can.

As to the Antenna T/R Relay causing receiver de-sensitivity that would not be common in my experience. The NC contact in this relay sees virtually no current unless the rig has been exposed to ESD. The contacts cannot be cleaned on the TS-530 FBR Ant T/R relay.

If you have the original clear plastic case Omron LZN4 flat pack Aux relay cleaning the contacts can be done, but in my experience will at best be a temporary fix. The LZN4 is no longer available, but can be replaced with a Aromat NF4EB or similar. I suggest buying one from Ken or Jim and replacing.

This issue is definitely a multiple repeat FAQ.

Bill,

What Terry said is 100%, however, as I am the lucky owner of two 530s, I had a similar problem years ago and it actually related to the RF att switch on the front panel. Try giving it a little wiggle\push in out before cycling through transmit and see if that helps. Mine just had a build up of age in it, I gave it a good blast of deoxit and cycled the switch numerous times, blew out with compressed air and it appeared to fix it, been good for 5+ years.

Remember if you going to go into the PA cage, make sure the radio is disconnected from power and you have discharged the HV, the voltages here are lethal! If it isn't the RF att switch, my money is on the molex connector, either dry joint or just dirty. As Terry said just replacing relays on a hunch is pointless in my opinion and applying heat the the foil track for too long can cause them to lift, so why introduce another problem without looking at the typical easy solve first.

41927. Re; TS830 Frequency Stability

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-27 14:17:26 UTC
From: hpdd709
Topic: 41927 Message: 41927

I have refurbished two TS830s and love both. Have received many fine compliments on audio quality and received signallevel. I don't have an external VFO to minimize the VFO drift. Both my radios drift 60 to 100 hz, even after a 45 minute warm up. But I must say, after the 45 minute warm up, the drift is at a minimum.

I was told that a modification can be done to the TS830 VFO to help eliminate the drift and bring the stability to the degree of the newer digital VFOs of the radios on the market today.

Does anyone know if there is any information out there?

Tnx,

Enjoy the hobby as I do.

73,

Mike/K3MG

Adding a VFO stabilizer is what's required. There
are two main units available. One is from Cumbria
Designs: http://www.cumbriadesigns.co.uk/ The
second is from K4DPK http://home.comcast.net/~k4dpk/

I have both units and they do as advertised.

Regards,
Mark

The trip to the electronics shop to find a VTVM was no good; the guy behind the counter thought it was some type of capacitor. I pointed to a Heath VTVM behind him, but all the stuff up there was antique display not for sale...

I'm looking at a popular online auction site and may have one in a little while.

I did notice that an unbuilt still in box IM-18 sold for $711...!

Kenwood gave just enough detail for casual user on the main functional blocks.
>
> ALC in the Hybrids is derived differently than most rigs that sample and rectify some rf output to develop the control voltage. With the hybrids the control voltage is always there derived from AVR board RF-1. We pull it down when grid current just begins to flow. Kenwood calls it Amplified ALC which is kind of a misnomer as the ALC transistor is not amplifying a signal it is acting like a variable resistor. I have a nice HP-410C 100 meg Z VTVM which I can actually watch ALC voltage pull down from RF-1 level as we increase RF drive. You can measure with a VTVM but it will pull down the voltage to around 2.6 to 2.7 vdc when you connect it and drives the S-meter upscale to around S3 to S4.
>
> You are not actually looking directly at Grid current when you peak the Drive control. Kenwood has no grid current meter shunts or grid current meter position. This isnt necessary for Class AB1 as there is no grid current. The grid requires no driving power only rf voltage swing. The moment that the driving envelope exceeds the dc operating bias offset and grid current begins to flow ALC bus line voltage is pulled down and TIF rf drive level is reduced. The cow just barely makes it out of the barn before it is pulled back!
>
> It is impossible to over drive the control grids of the finals and exceed the max grid dissipation.
>
> I think all the people who load by making sure the ALC is in middle of the black box or no more than the top of the black box ALC range are confusing it with another design or just dont understand how it works. On You Tube you can see some precautions about this presented by Extra Class holders. They have you peak in the black box and go back and check when done and adjust Car pot again. None of which is in the operating manual loading instructions. I guess they have good intentions. With a science or technical hobby need more than good intentions. Thankfully they are doing no harm to the rig. I have tried to

explain this too more than one of these fellows, but most are stubborn and continue to load as they understand how the radio works. Fortunately no harm done unless drive is marginal to begin with.
>
> Some old timers may do this as we were all taught not to exceed max 6146 grid current of approx 2.5 ma to 3.0 ma on our 1950/1960 vintage 50 watt CW Class C Grid Leak Bias transmitters. We had to go back after loading into our lite bulbs and check and adjust grid current reading level. Never wanted to exceed grid current or have loss of grid drive with grid leak bias rigs.
>
> None of that applies to a Hybrid. Its operating bias is fixed bias and not grid leak developed. Of course Kenwood could have been clearer on what they meant when the manual tells you to peak Drive control to maximum ALC indication. Almost every new owner asks immediately if that means max of black ALC box range or max on the meter scale. Just give a decent CAR Level so you can see a good peak as you tune the Drive stage to resonance. 2/3 to 3/4 scale is good place, but max on ALC box works just fine as well.
>
> The black ALC box is meaningless while loading the rig. It is there for SSB mode to ensure linear operation. When you talk up to the max of the black box you have approx 40ua to 45ua of grid current. Kenwood actually varies the ALC time constants to use it as a crude means of speech compression to increase your talk power without introducing too much adjacent frequency splatter. In no case should you talk rig up outside the ALC box. I try to keep it no more than mid-range. Technically when you have no indication you are operating at most linear place.
>
> I do not have a spectrum analyzer, but have asked the fellows who have L-pans and K3 rigs or similar to look at my signal while I varied the Mic gain for various ALC indications and no one sees any trash if I talk up to the max of the black box.

It doesnt have to be an IM-18. IM-28, IM-11 or even one of the older models. The basic circuit is very similar in all the units. There are couple of IM-18s on Ebay now in the $10 to $20 range. It would be better if you could find one with the original switchable probe if you can.

I usually recap the power supply, install NOS tubes, clean the switches and pots and often find the C battery has leaked and has corroded the contact spring and battery holder. If it is beyond cleaning up just dont install a battery. You dont need resistance function on it. Your DMM or VOM will be fine for resistance readings.

You can also look for an RCA VoltOhmyst model 97 or 98. They were kind of the Cadillac of VTVMs. I just suggested Heath as easy to get parts or a parts unit for them.

EICO, Knight also made VTVMs.

> >
> > None of that applies to a Hybrid. Its operating bias is fixed bias and not grid leak developed. Of course Kenwood could have been clearer on what they meant when the manual tells you to peak Drive control to maximum ALC indication. Almost every new owner asks immediately if that means max of black ALC box range or max on the meter scale. Just give a decent CAR Level so you can see a good peak as you tune the Drive stage to resonance. 2/3 to 3/4 scale is good place, but max on ALC box works just fine as well.
> >
> > The black ALC box is meaningless while loading the rig. It is there for SSB mode to ensure linear operation. When you talk up to the max of the black box you have approx 40ua to 45ua of grid current. Kenwood actually varies the ALC time constants to use it as a crude means of speech compression to increase your talk power without introducing too much adjacent frequency splatter. In no case should you talk rig up outside the ALC box. I try to keep it no more than mid-range. Technically when you have no indication you are operating at most linear place.
> >

Some of us learned about vacuum tubes through audio frequency applications before becoming interested in RF. My HiFi is all tubes, and as a guitarist, all six of my amplifiers are tube amps. I used a 1963 republication of the revised 1962 printing of the original 1955 Navy training course NAVPERS 10087-A to learn - well written, clear, direct, designed to train for practical results.

Even we who are fairly knowledgeable about tube amplification are just seeing the tip of the iceberg of what is entailed in transceiver circuits. I'm glad the gray beards here are so willing to devote their time and energy to helping all of us.

To add to Terry's response, a few additional Heathkit VTVMs are the IM-11, IM-17 (all solid state battery powered) and V7A and the Eico 232.

Another VTVM that's nice to have is the IM-21 that measures AC voltages from .01 to 300VAC. AC volt meters such as the IM-21 are not professional quality meters but they do serve a purpose and provide a means to measure AC voltage, especially aligning receivers for a peak audio signal at the speaker. Probes for AC VTVMs such as the IM-21 use Banana Plug probes, one for Positive and one for Negative.

The Heathkit VTVMs were basically the same with only a few changes made to the various models. I see Heathkit IM-18 VTVMs on ebay quite often.

If the VTVM doesn't come with probes then you will have to find the original probe or make them yourself, they're not difficult to make. The probes typically have a 1 Meg 1/2 watt resistor in series with the probe's tip. The resistor is required for DC voltage measurements but not required for AC/Ohms. Therefore, you can make 2 probes, one with the resistor and one without. You can also make a probe using a piece of small diameter PVC pipe with a slide switch embedded/mounted inside the PVC probe housing that switches the resistor in and out of the probe. Again, they're not difficult to make.

Most VTVM are designed to measure up to a maximum of 1500 volts (AC/DC) and resistance values from R x 1 to R x 1 meg.

Hi Mike: Yes you are correct can make your own probes, but couple of precautions.

1. Make sure what ever "pen body" you use has sufficient dielectric strength. You are going to be measuring 900 vdc anode voltage so cant have any breakdown or tracks. Heath had liability so pretty safe bet that the probe body they used would easily withstand well in excess of 1500 vdc. Their switch had no exposed metal on outside of probe.

2. Make sure your electrical connection from probe tip to test lead is well within whatever you use for a probe body and has some kind of strain relief so it cant pull out.

3. Do not skimp on the test lead wire. Many cheap meters are actually dangerous in my opinion. The weak links are the probes and internal connections and when they use small gauge plastic insulated test leads. I would recommend you use something equivalent to Belden 5KV test prod wire. It is very flexible and good dielectric.

4. DO NOT be tempted to eliminate the 1 meg series resistor in the probe tip body or move it inside the meter. It is there for a reason. This series resistor decouples the test lead shunt capacitance so that when you touch the probe tip to the grid of an oscillator tube to measure bias voltage you do not pull the oscillator off frequency or worse yet shut it down. There are other examples, but you get the idea.

Finally this is not probe related.

If you are going to get serious about servicing Kenwood Hybrids or other tube boat anchor rigs I highly recommend you get the real Cadillac VTVM and that would be a HP410B or HP410C. I have a refurbed 410C with the FET board updates that replace the old chopper. These meters have over 100Meg input Z. This allows you to get on the AGC bus (rail) without affecting the gain controlled stages. Again these meters are for folks with adequate disposable income or who have a serious RF service bench for tube rigs. A refurbed unit can go for $200 to $300. You can pick up non-refurbed for around $75 to $100.

If you think your current multimeter is adequate just connect it to your Hybrid AGC bus and watch what happens to your S-meter and listen to the receiver. A multimeter with 2 meg input Z will pull the AGC bus down to around 1.25vdc and drive the S meter to 10 over S-9 or higher and the RX noise will fall off and affect weak signal copy. A 5 meg input Z meter will pull the bus down to approx 2.4 vdc and run the S meter up to around S7 plus.

So as Mike says no reason you cant hombrew your own VTVM probes. Just make sure the electrical and mechanical design is safe.

41934. TS 820 problem with dipping the final

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-27 21:53:02 UTC
From: eoxer
Topic: 41934 Message: 41934

Hello

Tried loading the final but after several attempts (no dip) with adequate drive and idling current per instructions, fuse blew and smoked a 20 ohm resistor part of R2 (10 ohm 1 watt). I can replace the resistors and fuse. Any ideas on why it might have blown other than the part went bad. Other resistors a in R2 and R3 of the final board appear okay. R2 is apparently made up of two half watt 20 ohm resistors to get 10 ohms at 1 watt. Thanks for any help with this.

You have blown a cathode meter shunt resistor. What do you know about the final tubes? Is this first time to try to load with these finals?

Most likely a final has arced over. When these tubes arc over you have approx 850 volts from Anode to Cathode and the cathode meter shunts along with the power supply ESR is all that limits the fault current. I = 850/5 = 170 amps. That is why the primary fuse blows and the resistor(s)can fail violently.

I dont like to re-use any finals that have arced over. Some folks replace both meter shunt resistors and re-try and it may work 2nd time around. If you do this and the two 10 ohm meter shunts fail again I would toss these finals.

Without a dc hi-pot tester there is no good way to check your finals.

I place a series string of 3 silicon diodes across my cathode meter shunts to limit the voltage drop to approx 2.1 vdc. This should prevent the resistors from failing and protects your Ip panel meter.

I forgot to mention. Normally I do not recommend installing any mods in the hybrids. However after experiencing multiple cathode resistor failures with a variety of 30 to 40 year old 6146 finals I decided to install some arc over protection.

In addition to the diode string across the cathode resistors I also installed a Glitch resistor in the anode supply and MOVs on each screen grid.

I used a couple of 5.6 ohm Ohmite Type OYs in series on a phenolic terminal strip at output of the HV filter caps. Now with 5 ohms cathode resistance, 11 ohms glitch resistor, and 5 - 10 ohms power supply ESR I have approx 20 to 25 ohms limiting fault current. So I = 850/20 = approx 45 amps. Primary fuse will still blow but lower fault current isnt as hard on HV filter caps, HV rectifier diodes and the power transformer.

Wont go into the calcs for sizing the MOVs here. I think Mark Gilger WB0IQK has developed a technical bulletin on this mod and posted it on his website?

Terry's modification is posted here:

http://wb4hfn.com/KENWOOD/Articles/Technical_EX-004.pdf

I've installed this in several problem radio's,
and once installed I never had another failure. It's worth the time to install.

Regards,
Mark, WB0IQK

Both my hybrids drift a bit, which is the nature of the beast I guess...:)
Replaced some of the known components and it did get better.
Did find a couple options on the net that help "cure" the drift.

****** K4DPK's VFO Stabilizer *******
****** X-lock by Cumbria designs ****

Does anyone have experience with either?

The hybrid owners operating manuals provide the design specs for warm up and long term drift. You can check your drift against those published specs. Most rigs meet or exceed those specs, however some do not. I have two TS-830s and one is very quick to stabilize and has very little long term drift. It exceeds the specs and is essentially lock solid in very short time and the other will drift for hours down freq and then lock and then start back up freq. Never does completely settle down.

By the way VFO drift is not caused by a dirty or corroded rotor shaft contact wiper. That situation causes drop out or noise or jumping in frequency. Two very different conditions.

Excessive drift is almost always caused by one of combination of four things.
1. 9vdc regulated supply problem
2. Bad VFO PC board ground connections
3. Bad VFO PC board components typically fixed cap or fixed TC caps) 4. Dirty/leaky PC board surface

If you have remote VFO easy to see if problem is 9 vdc. If remote does not drift and internal does then not due to 9vdc as is common supply. Also, if no remote VFO for comparisons then internal VFO can be temporarily powered by one or two fresh 9vdc batteries in parallel to rule out or confirm the rigs regulated 9vdc as the source.

Some report success loosening and tightening the VFO PC board mounting screws and with cleaning both sides of the PC board. Some use alcohol and others use lacquer thinner. I would be very careful with either so you dont melt any components.

Performing VFO drift Compensation (TC) is a little bit of science and art. Very time consuming and frustrating. Not easy to do anymore as type NPO,N,and P TC caps are not readily available. You can see the typical problem TC caps in the VFO if you look where low Pf value caps have been placed in parallel to split the rf current heating affect and you can tell a TC cap by its prefix. Look on the parts list legend and you will see the various TC caps that were employed. A type CC45 is a TC cap. Look at the parts listing for your VFO and can see locations of all. Do not sub a regular cap for a TC cap.

You can put VFO on bench and power up and bring soldering iron tip close to each cap and see which ones are more sensitive and replace them. I have spend hours subing P and N types for NPOs. By the way a modern version of the NPO is a COG.

I have no experience with installing these "Huff and Puff" circuits. Mark Gilger has installed both common units and has very good experience with both.

I may end up installing one for my one VFO that I have affectionately labeled my DMO or "dont move over" unit!

There is an EICO 249 VTVM listed on QTH by WA0VRC this am for $25. The manual is available on BAMA. This is a nice unit with meter that even has a P-P scale. No idea what condition it is in or if he has the probes.

My VFO drifts 460 Hz in first 45 min. But VFO-230 is very stable, it drifts only 14 Hz in same range.

The VFO-230 is not powered by the transceiver like the VFO-240 is. The VFO-230 has its own built in power supply. The VFO-240 requires power from the transceiver.

The VFO-230 is also a digital VFO but the TS-530 and TS-830 internal VFOs and the remote VFO-240 are all analog and all 3 are powered by the transceiver.

Terry and Mark,

Thanks again for the quick reply on the TS-820.

No more problem with exploding resistors. Both have been replaced. I'm also back to using the original 6146's... back to square one with inability to dip the final. There appears to be adequate drive and even an intermittent output that lights a 100 watt bulb nicely. I'm thinking the finals need replacement or is there something else I should consider?

73,

Ed, W8EO

Does it behave like this on all bands? Have you pulled the Antenna TR Relay and cleaned the contacts? If not, I would try that first. It is under metal shield can near final board. Carefully clean by pulling printer paper wetted with contact cleaner thru the contacts. Can also temporarily swap with the Aux relay as they are the same. Pull and clean both. Wont hurt to do as preventive maintenance.

Regards lite bulb dummy load we used them for years as tuning indicators and dummy loads. While they will work for testing your rig absent anything else, I suggest you buy or build a "real" dummy load. Your problem is another reason I suggest buying or building a wattmeter to help trouble shoot these kinds of problems. Looking at Ip meter is ok but sure nice to see what level of actual RF you have at that SO-239 connector.

Biggest problem with Lite bulb dummy load is that it can radiate significant distant and cause on band interference. If you are going to use it to test your rig you need to listen on frequency first.

Contrary to popular opinion it will not hurt your tube rig. Would not use with solid state finals. Yes the filament resistance changes from cold to hot, but does so very quickly so not a real problem. At HF frequency it has very little reactance and is nearly unity power factor. There are several WWII surplus dummy load/tuning devices that used an incandescent lamp and viewing lense to load and test transmitters up to the VHF range. QST did some testing many years ago before non-inductive resistor dummy loads and watt meters were common place in ham shacks.

Here is some of the details from that testing.
60 Watt bulb Cold = 27 ohms Hot = 219 ohms SWR approx 4 to 1
100 Watt bulb Cold = 20 ohms Hot = 132 ohms SWR approx 2.6 to 1
250 Watt bulb Cold = 4.5 ohm Hot = 53 ohms SWR near 1:1 (bulb not easily found today)
Can also can place bulbs in parallel. For example 3- 60 watt in parallel for approx 73 ohms
Brilliance will be approx 3/4 normal with RF ac applied as opposed to 60hz ac.

Summary: Start by cleaning Ant TR relay and buy or build a dummy load.
Can find a Celwave watt dry type on Ebay for around $50. These are nice as they have a BNC connector test port that is a capacitive tap that can use to drive a rf meter or your O-scope. I have one rated at 250 watts with very good duty cycle.

As a point of interest the military dummy loads like the AN/URM-13 and DA-38/USM-13 used Carbon Filament bulbs and not the tungsten filaments of today. Their hot/cold resistance ratio is the inverse of todays common (and soon to be extinct if his excellency has his way)tungsten lamps. These dummy loads used four Type 46 carbon filament lamps in parallel. The resistance of these lamps changed from approx 400 ohms cold to approx 170 ohms hot in just under 0.10 seconds. The resistance stayed pretty constant from approx 1300 degree C to 1900 degrees C. So 170/4 = approx 43 ohms. Close enough to 50 ohms.

You see these surplus military units from time to time at hamfests. A good one will come in metal case toolbox with set of spare lamps. The unit looks like a small metal coffee can with a coax connector on one end and the other end is open with the four lamps in recessed sockets so operator could see the brilliance as they tuned the transmitter tank circuit. Would simply tune for max brilliance and the modes then were CW and AM and on AM could watch the flashing with modulation. I am not sure but believe they were rated at 20 watts continuous duty. Probably conservative as most military ratings. Of course they would radiate, but military apparently wasnt too worried about inteference.

So if you want to continue to use lite bulb tuning aid/dummy load get yourself some Robertson Carbon Filament lamps in place of your modern tungsten filament lamps. Robertson lamps were used in the 50s as heat lamps. I see one listed on Ebay now for $66.00. Ouch!

Sorry Gordon back to Hybrid stuff now!

I have a Heathkit IM-18 on the way. I have downloaded the user manual with schematic and am studying both while waiting for the VTVM to arrive. Looking forward to learning how to use it troubleshooting the ALC problem.
Sure to be back with questions about procedure and interpretation of findings soon.
Thanks,
Paul
AD5FT

>
> Paul: Couple of things. Good job on getting the DC voltages. VOMs typically have 50,000 ohms/volt sensitivity so OK for plate and screen voltages but not good for ALC or AGC bus and getting on grids of vacuum tubes.
>
> 1. Suggest you get a DMM or a VTVM to get higher input impedance. I prefer the old Heath VTVMs like a IM-18 as it has 11 meg input Z and wont load down your readings and a large analog scale to see peaks and nulls. I suggest Heath as they made 10s of thousands so can always buy a spare for a parts unit. A good DMM also has its place for the DC readings that you just took. Most will have a 10 meg Z, but some do not. A cheap Harbor Freight measures at just under 1 meg and some have different Z depending on the meter range.
>
> 2. I assume you have the Tuner in Bypass? Tuner watt meter is fine.
>
> 3. I assume you have advanced CAR Level Pot full CCW and peaked the Drive Control. It may not peak at 1200.
>
> 4. Your DC readings look good. You can see that you have proper switch over from cutoff to operating bias voltage on the Driver Tube and the Finals.
>
> 5. I assume that your -57.5 vdc bias voltage is with 60 ma resting plate current. At -57.5 you will need -57.5/1.414 = 40.67 rms rf volts drive at 6146 Pin 5. So anything less than approx 41 rf volts drive and you will have no ALC meter indication. Anything greater than 41 rf volts and you should see ALC indication assuming the ALC metering is working. Suggest you follow previous suggestion to clean aux relay contacts. Good idea to clean them as easy to do and AGC and ALC bus line is switched by this relay.
>
> 6.With the lower RF output you could use a single germanium diode RF probe to take the TX Level diagram readings to see where losing it at. Normally suggest use a two or three diode probe to get on plate of 12BY7A or grid of 6146 finals so you do not exceed the peak inverse voltage of the single diode. See N5ESE to make a probe or buy Hendricks kit or buy used Heathkit 309-c etc off ebay.
>
> 7. You cannot accurately measure TIF signal from IF board using RF probe as it is too low a level (approx 35 mv). Absent RF millivolt meter use an O-scope to measure TIF. If you have good RF level at output of TX Mixer safe to assume have adequate TIF level.

Topic: 41947 Message: 41947

Greetings, I am new to the Yahoo KENWOOD TS-520_820_530_830
group. I have a TS-830S. I recently became interested in digital modes, and I've done a bit of searching here, but I'm still pretty confused. I'm receiving PSK31 just fine. I've run an audio cable from from the SP-230 to my sound card. Fldigi does a fine job of decoding.

It's on the transmitting side that my confusion starts. Since PSK31 has a very narrow bandwidth, how do I tune my 830 to be dead on the receiving frequency so that I can transmit and be heard at the other end?

I haven't made any hookup yet from the sound card line out to the mic on the TS-830S yet, but it looks like a gadget like the Signalink can handle this pretty well. Before I spend $, I just wanted to get a handle on how successfully PSK31 can be managed with the TS-830S.

Thanks and 73's,
KK4MZZ
Milton

41948. Re: [TS-520_820_530_830] VFO stabilizer or lock for the hybrids...good, bad...experience?

Bart-

I use an X-Lock in an old Swan Cygnet 270 that I restored. It makes all the difference in the world with this rig. Within 5 minutes of turning it on, I can set a freq and it stays there and that rig is almost all tubes with only a couple of transistors in the VFO. I've been very happy.

I will say that it does take a little bit of work to get it installed. With the 270, I had to go into the VFO and change some of the pad caps they had across the trimmers for the various bands so I could net the VFO on freq with respect to the dial.

I've thought about putting one in my 530, but not sure if RIT would play nicely so I decided to leave it be. The 270 does not have RIT.

Paul: Very good. A good first piece of test gear for Hybrid work. Dont forget to measure rf drive levels you will need more than just the IM-18. You will need two rf probes or a single switchable one. A single diode for the TX Mixer output at MD on RF board and three diode probe to measure output of Driver tube at DP and at control grids Pin 5 of the Finals. Can make or buy the probes.

Do a good visual on the IM-18 internals and check the tightness of the terminal strip and ground lug hardware. Clean the pots and switches. Later may want to replace C1 electrolytic filter cap and the 6AL5 and 12AU7 tubes.

The cal procedure is pretty easy and no battery needed unless you want to use the resistance function.

> >
> > 1. Suggest you get a DMM or a VTVM to get higher input impedance. I prefer the old Heath VTVMs like a IM-18 as it has 11 meg input Z and wont load down your readings and a large analog scale to see peaks and nulls. I suggest Heath as they made 10s of thousands so can always buy a spare for a parts unit. A good DMM also has its place for the DC readings that you just took. Most will have a 10 meg Z, but some do not. A cheap Harbor Freight measures at just under 1 meg and some have different Z depending on the meter range.

> >
> > 5. I assume that your -57.5 vdc bias voltage is with 60 ma resting plate current. At -57.5 you will need -57.5/1.414 = 40.67 rms rf volts drive at 6146 Pin 5. So anything less than approx 41 rf volts drive and you will have no ALC meter indication. Anything greater than 41 rf volts and you should see ALC indication assuming the ALC metering is working. Suggest you follow previous suggestion to clean aux relay contacts. Good idea to clean them as easy to do and AGC and ALC bus line is switched by this relay.
> >
> > 6.With the lower RF output you could use a single germanium diode RF probe to take the TX Level diagram readings to see where losing it at. Normally suggest use a two or three diode probe to get on plate of 12BY7A or grid of 6146 finals so you do not exceed the peak inverse voltage of the single diode. See N5ESE to make a probe or buy Hendricks kit or buy used Heathkit 309-c etc off ebay.
> >
> > 7. You cannot accurately measure TIF signal from IF board using RF probe as it is too low a level (approx 35 mv). Absent RF millivolt meter use an O-scope to measure TIF. If you have good RF level at output of TX Mixer safe to assume have adequate TIF level.

RIT works correctly using either of the two Stabilizers.

Milton,

I have not used digi with the TS-830S but I have used fldigi with my
TS-120S with no problem; should be no problem with a hybrid.
I use a Yaesu 897 for voice and digital with a Signalink on 6m ; we have
two digi nets a week plus a bulletin and also use RMS Express on 40m.
I use the 830 strictly for voice.

The computer does all the tuning and handles the bandwidth issues. You just set the VFO to the packet freq and fine tune with the computer program.
The biggest problem I have read about is the stability of the VFO in the hybrid radios is not good enough for the very narrow psk signals. If you just drft a few Hz you loose your link with the other station.

Subject: [TS-520_820_530_830] PSK31 and TS-830S

Greetings, I am new to the Yahoo KENWOOD TS-520_820_530_830
group. I have a TS-830S. I recently became interested in digital modes, and I've done a bit of searching here, but I'm still pretty confused.

It's on the transmitting side that my confusion starts. Since PSK31 has a very narrow bandwidth, how do I tune my 830 to be dead on the receiving frequency so that I can transmit and be heard at the other end? Before I spend $, I just wanted to get a handle on how successfully PSK31 can be managed with the TS-830S.

Thanks and 73's,
KK4MZZ
Milton

Milton,

Before you start operating PSK31, I recommend you take some time and
watch the video at the link below FIRST. I think the video will answer a
lot of your questions about PSK31.

http://www.howtomakeonline.org/QEMR9MoneyhGBpQj/Introduction-to-PSK31-Receiving.html

If you have any questions about the video come back here and ask, don't
"assume" anything, you could be making a wrong assumption.

I've thought of buying a crystal to put into one of the fix channel
slots for 14.070 (the normal psk31 freq). Would that fix the stability
problems?

Yes it would.The crystal frequency for 14.070 is 5.570Mhz. The formula for calculating the crystal frequency is on page 21of the TS-830 operator's manual.The crystal "replaces" the VFO when operating the FIX CHANNEL feature.

You can purchase new crystals from International Crystals in Oklahoma City, OK.

http://www.icmfg.com/

Give them a call, they have a toll free 800 number, to discuss pricing and lead times.

Hello to the group! I have an 830 that had been putting out full power until recently. One day fine the next day 25W output only. The pre-select/drive peaks like normal. Tune/load controls behave normally. Tune/load control shafts are in alignment and rotate normally. HV is normal. Everything seems completely normal except for low power. This condition exists on all bands and all antennas. I've also checked all jumper cables. I put in my spare finals this evening and no change. Any ideas will be very much appreciated. 73...Barry KF4WGR

1. What is Ip reading?

2. Do you have another wattmeter to try?

3. Do you have a rf probe and VTVM or an O-scope? If so can measure the voltage across your 50 ohm dummy load resistor. P = E squared/R.

100 watts output you should measure approx 71 rms rf volts (200 P-P) and 25 watts you should measure approx 35 rms rf volts (99 P-P).

I'll second number 2 below! A few months back, this same scenario drove me nuts for a few days, and it turned out to be a bad wattmeter...felt both silly and glad at the same time.

Thanks to encouragement from a few folks on this list, I bought a new wattmeter and realized that yes indeed, my other meter had failed.

41961. TS 530SP Dial Speed

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-04-30 07:14:04 UTC
From: C A
Topic: 41961 Message: 41961

Just replaced a '430S with a mint '530SP. Absolutely beautiful rig that lives up to its reputation. The only "con" I have is the tuning speed which is entirely too fast for an old man. Difficult to stop on freq. The '430 was 10kc per revolution which was a piece of cake, the '530 is 25kc per revolution. By any chance is there a mod to slow it down?

Tnx

I'll check Ip and I do have another watt meter I can try. I'm using a Wavenode station monitor and I suppose the sensor could be bad. I do have an VTVM I can use to check the voltage across the dummy load resistor. Good ideas, thanks!

Will need 3 diode RF probe and VTVM. At 71 rf volts the PIV will be approx 200 volts so a single 1n34A diode (50 volt PIV rating) will not like to measure 71 rms rf volts across your dummy load. Unfortunately I learned this the hard way many years ago after I made my first homebrew rf probe!

Is your Wavenode displaying Reflected Power at same time it is displaying 25 watts Forward power(I assume average watts)?

If so, what is it telling you. I have no experience with the Wavenode and know nothing about its reliability.

If you get a Heathkit Cantenna it has a built in RF detector. It uses a resistive divider.

Hi Terry,

Tnx for the info. Did some inspecting and cleaning of contacts mostly on the bandswitch which helped alot. The rig is now performing as it should and loading a G5RV and making contacts with good signal reports on cw and phone. Thanks again.

73,

Ed, W8EO

>
> Does it behave like this on all bands? Have you pulled the Antenna TR Relay and cleaned the contacts? If not, I would try that first. It is under metal shield can near final board. Carefully clean by pulling printer paper wetted with contact cleaner thru the contacts. Can also temporarily swap with the Aux relay as they are the same. Pull and clean both. Wont hurt to do as preventive maintenance.
>
> Regards lite bulb dummy load we used them for years as tuning indicators and dummy loads. While they will work for testing your rig absent anything else, I suggest you buy or build a "real" dummy load. Your problem is another reason I suggest buying or building a wattmeter to help trouble shoot these kinds of problems. Looking at Ip meter is ok but sure nice to see what level of actual RF you have at that SO-239 connector.
>
> Biggest problem with Lite bulb dummy load is that it can radiate significant distant and cause on band interference. If you are going to use it to test your rig you need to listen on frequency first.
>
> Contrary to popular opinion it will not hurt your tube rig. Would not use with solid state finals. Yes the filament resistance changes from cold to hot, but does so very quickly so not a real problem. At HF frequency it has very little reactance and is nearly unity power factor. There are several WWII surplus dummy load/tuning devices that used an incandescent lamp and viewing lense to load and test transmitters up to the VHF range. QST did some testing many years ago before non-inductive resistor dummy loads and watt meters were common place in ham shacks.

The Heath Cantenna detector circuit dc output voltage provides a relative power indication. It is very frequency dependent. If you apply a fixed level of RF power at 3.5 mhz it will give an indication on your meter. Apply that exact same level of power at 29mhz and it will give a much higher meter deflection.

For example at 100 watts into the Cantenna on 7.2Mhz the detector will produce approx 2.25 vdc and at 14.2Mhz it will produce approx 1.35 vdc. Unless you develop a spread sheet for your particular Cantenna the detector circuit is not very useful.

No need to rush out and buy a Cantenna (I have them at operating position under bench in oil catch basins)and use Cel-Wave dry type on service bench with capacitive divider tap to drive O-scope.

Very simple to read the IR drop across your dummy load resistor. With any 50 ohm dummy load that you have just connect a coaxial Tee at input to your Dummy Load and use your O-scope or RF probe/VTVM or RF Millivolt meter to measure from the open center pin of this Tee to the connector body shell. No need to open up your dummy load to read the IR drop across the internal resistor. With coaxial Tee at input you should read approx 70.7 volts from center pin to shell if you have 100 watts input to the dummy load and it is close to 50 ohms resistance.

The Cantenna circuit can be modified with appropriate caps to provide frequency compensation and change the divider string and add a cal trim pot and then can be calibrated to drive a ua meter movement to read wattage. I think CQ or 73 Magazine had an article describing this mod.

Eureka! Much thanks to Terry and the group, the problem is apparently a bad RF sensor for the Wavenode. I have a spare I put in line and all is well. Another clue that there was nothing wrong with the xmit was that my amp's plate and grid currents were normal. Thanks again for the help! 73...Barry KF4WGR

41968. Use of "Canned Air"

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

I have been looking for Canned Air. I have assumed it was air.

I left a can of a "gas duster" at my local Walmart because it listed another ingredient with a long name. I finally bought a can of compressed "Dust Away" from a photo shop. It consists of 100% difluoroethane as far as I can interpret the label and the associated MSDS sheet. It is recommended for removing dust. I think that that is the same as the Walmart product.

Mike, Is this the product that you are recommending?

Sorry got my dc output voltages copied wrong from my chart. I even forgot I had developed one. Should have been 2.25vdc on 14.2 mhz and 1.35vdc on 7.2 Mhz. The higher you go in Freq the higher the dc output voltage.

Dont forget the voltage you want to read across the dummy load is RF and not DC. Power = E squared/R. To be accurate you can measure the resistance of your dummy load from center pin to shield of the SO-239 connector. Very few are exactly 50 ohms.

All I was trying to do was to provide an easy way to see what the actual output power is in the absence of another calibrated wattmeter.

If you really have 25 watts output then you would read approx 35 rf volts at the coax tee.

I have been using Walmart canned air for some time and I admit a bit nervous about it. As you note the MSDS sheet shows that it is flammable and should be used with adequate ventilation.

I have never found anything that really works as well as good old Freon 113 for cleaning off solder flux on the trace side and oily/greasy dirt on component side of PC boards.

I have discovered that if you tip the Walmart can slightly while blowing off the board you will release the propellant and it does a very good job of cleaning off oily dirt from boards. It evaporates quickly. Just have to be careful and not get frost bite.

One of my big concerns is I do not know if there is any possible reaction with Diflouroethane and the aluminum canned filter caps.

I am interested in the experience/recommendations of other members. I dont really have any other source of dry air.

It consists of 100% difluoroethane as far as I can interpret the label and the associated MSDS sheet. It is recommended for removing dust. I think that that is the same as the Walmart product.

Terry & Group,

  I have been using "DUST OFF" for the past 3 years. I buy it at "Costco" by the 6 pack. It also is based on diflouroethane. I have not suffered any problems or noticed any difficulty with it. It is used mostly for blowing off band switch wafers, pots etc. after using Deoxit for the first cleaning. As I stated prior, the makers add noxious "stuff" to make it difficult for the junkies to high on it...even says so on the can....go figure. The label on the can states not to tip it when spraying or the "liquid contents" may come out. I must admit...the "contents" do make a good solvent...just doesn't last long.... evaporates in a flash.

Subject: [TS-520_820_530_830] Re: Use of "Canned Air"

I have been using Walmart canned air for some time and I admit a bit nervous about it. As you note the MSDS sheet shows that it is flammable and should be used with adequate ventilation.

I have never found anything that really works as well as good old Freon 113 for cleaning off solder flux on the trace side and oily/greasy dirt on component side of PC boards.

I have discovered that if you tip the Walmart can slightly while blowing off the board you will release the propellant and it does a very good job of cleaning off oily dirt from boards. It evaporates quickly. Just have to be careful and not get frost bite.

One of my big concerns is I do not know if there is any possible reaction with Diflouroethane and the aluminum canned filter caps.

I am interested in the experience/recommendations of other members. I dont really have any other source of dry air.

John,

I'm not in the shack at the moment, that's where I keep the canned air, but the can is Green and white color and sold at Walmart. Terry's right, if you tilt the can a bit the propellant will comeout as "White frost" and is very coldso don't allow it to get on your skin. If you shake the can it turns cold.

I have never had any problems using it on any metal, PC boards either component or foil side, even aluminum.

Chris

The 520 will not rcv WWV/JJY on 25Mhz. It will only rcv it on 10Mhz. Look on pages 11 & 12 and also Section 4.5 (page 20) of the operators manual.
If you do not have one, you may find one at: n6wk.com Gordon has many manuals on his site that are free...THANKS GORDON!!!

No offense but you are not making "dry" air. Anytime you compress air you have moisture in your tank. That is why they place a brass petcock on the bottom of the tank so you can blow it out. I have nice air compressor in my garage and it has the standard "moisture" separator on the output, but it does not produce Dry or moisture free air. It is just a water trap with a drain petcock on the bottom.

I would never use my shop air to blow off my boards or my rig. I suppose you could if you then placed in the oven?

There are couple of ways to dry the air from a compressor so that is is essentially moisture free. A Desiccant unit with replaceable cartridges will run you about $600 from Northern Tool and a Refrigerated Dryer will run $1500 to $2000 depending on CFM.

This is the reason people are interested in moisture free canned air at the service bench. They are looking for the ease of use. I dont want to run a compressed air line from garage into house and cant justify buying a air dryer. Take a look on You Tube and you will see a variety of home made dryers. Not sure how they measure the output air moisture content to confirm these things are working.

One last thought on canned air.

You could go to computer shop and buy Belkin Blaster brand. It is $8.99 for 12oz can. It is 100% 1,1,1,2-Tetrafluoroethane which is R-134A auto air conditioner refrigerant.

Could probably buy small cans of R-134A cheaper at auto stores or Walmart, but have to be careful that it is just plain R-134A with no leak sealant or compressor oil additives. Would need to buy cheap can tap kit to use it.

You can buy a 30lb cylinder of R-134A at Sams Club or Rural King for around $100. That is equivalent to 40 Belkin cans.

OK enough of this.

I really think that it depends on where you live. When you only have a 10% relative humidity, high water content in your compressed air is NOT an issue.

When I worked in the auto shop years ago, we had a paint booth also. The filters for moisture are not all that expensive, but they ae when you go through a filter every other day or so. As a result, we used the container for the filter, and shoved a large roll of Toilet Paper in it. This was more effective then the original filters.

Thanks for the information, everyone. It looks like I have the equivalent of what is recommended. I happen to live and shop in Canada where prices are often different, and seldom less. Although the comparative prices between brands may have the same ranking, so Terry's suggestion is worth investigating after I run out of this can.

John

Subject: [TS-520_820_530_830] TS-520 vfo to 25mhz

I just recently acquired a TS-520 and am still learning how to navigate the vfo knob. I am trying to check the receive of the unit by tuning to 25mhz to listen to the clock. What actual settings would I need to use?

The TS520 (no S) goes to 10-10.5 mHz band when you press the WWV/JJY button.
Set your VFO dial to 000 to hear WWV at 10 .000 mHz.
yOU can also hear the 30M band (no transmit) when you push the WWV button.

If you didn't get the user manual with the rig you will get lost , download one and read it before you get into trouble and blow out final tubes.

I am not sure how the input air in Nevada helps the fellow in Canada or me in Michigan?

Actually there is another reason not to use your air compressor to blow off your rig and your boards and that is oil mist. Crankcase oil vapors are carried over into the air. You dont want to blow oily air on your rig.

As far as 10% humidity being a non-problem that is not entirely correct. It has been 40 years since I had Thermo so you may want to check my facts.

Your compressor will suck in 7 cu ft of Nevada air @ 0 psig and compress it to 1 cu ft @ 100 psig and at the same time elevate its temperature considerably. So the water vapor that was in 7 cu ft is now in 1 cu ft. As that air leaves your compressor and enters your tank it reaches its dew point and condenses in the tank.

Rough calcs show that there will be 0.40 lbs/1000 cu ft @ 100 degrees F and 10% RH. Water is approx 15oz/lb. So if your compressor is 10 scfm in about 1.5 hours it will produce about 6 oz of water. Not a lot of water, but how much water vapor is too much to apply to your rig and boards?

So I stand by recommendation it is not good practice to blow out your radio with compressed air from a common home/garage air compressor with no oil separator and no air dryer. Not to mention accidently hitting delicate components with 100 psi.

Sorry to bore the Scare Crow in Oz with so much Hot Air. Technical subjects like ham radio can be so boring.

The primary use of the canned air is not to clean the rig or boards. That is secondary. It is to remove contact cleaner that was used on VFO rotor shaft wiper contact, or contact cleaner that was sprayed on dirty bandswitch contacts.

People have been using soap and water and dishwashers and garden hoses and drying in the sun and placing in the oven for years with no ill affects. Nothing to do with using canned air to remove contact cleaner residual spray.

This is a different subject. I confused the two when I discussed using the canned air propellent to remove flux and greasy dirt by tipping the can. We are talking about not using compressed air from home compressor to remove this residual contact cleaner.

Sorry for the confusion.

I have a water separator, air scrubber, (Cartridge filter based to remove any oil in the line) in the line running to my bench. The line that runs to my auto shop, has an oiler in line so I don't run my air tools 'dry'. I have been blowing out computers, servers, radios, etc. for years with no adverse affects. I can see an issue where one runs an 80% relative humidity, but not here in the desert..your figures may be accurate, but the amount of moisture that is 'blown into' my air line from the shop compressor, is so small as to be inconsequential. As per 100 PS, there are such things as pressure restricting nozzles, you know! My shop is not a commercial clean room, so I don't sweat the small stuff. <<GRIN>>

You will probably have an issue with this...If have a radio that comes out of a smoker's house, and is encased with yellow sticky, stinky slime, I strip the tubes, VFO, meters and anything else water can damage, and then put the parts in the dishwasher and run it through a clean cycle. (Of course, I have to do it when the wife isn't watching, or I will have to listen to her give me hell!) Everything comes out like it came from the factory. I then 'bath' the parts in an alcohol bath for 30 minutes, take it out, blow it out and let it sit in the open air for a day or five. Never had a problem. (Got the dishwasher idea from some friends that were radiomen in the Navy aboard ships...that's how they cleaned their gear...great idea.

I only used air compressor to blow dust out of heatsink fins on big rack mount power supplies, solid state amps.and .high power transmitter antenna combiners !
The heavy duty commercial stuff could take it.
The receivers, exciters, modems, digital multiplexers, switches and routers got the little dry air spray cans used on them.

I should have elaborated on "Nevada air" being canned and shipped to your home location for a nominal postage and handling charge !

Joe...WKRN

The dishwasher idea is a good one, I've used it for well a long long time.

About two years ago a friend of my wifes mother knew of a guy who had gone silent key and the relatives were simply tossing the "old junk". By the time I got there I had to spend most of the afternoon diving in the specially rented dumpster...and I got everything but wow was some nice gear a mess.

We have on our farm a "egg washer" which is really a old dishwasher which has been modified to allow "no hot water" for washing the 200 or so eggs we get a day! I followed exactly what you did either strip wash and then alcohol...and everything stabilized nicely.

I have started to restore a lot of it and its going good.

BTW on a totally different subject; my company is going to manage some flight operations in both Bangladesh and India and I am going to spend sometime in both countries...so you should be hearing from me as SL2 and VU

Joe...WKRN

The dishwasher idea is a good one, I've used it for well a long long time.

About two years ago a friend of my wifes mother knew of a guy who had gone silent key and the relatives were simply tossing the "old junk". By the time I got there I had to spend most of the afternoon diving in the specially rented dumpster...and I got everything but wow was some nice gear a mess.

We have on our farm a "egg washer" which is really a old dishwasher which has been modified to allow "no hot water" for washing the 200 or so eggs we get a day! I followed exactly what you did either strip wash and then alcohol...and everything stabilized nicely.

I have started to restore a lot of it and its going good.

BTW on a totally different subject; my company is going to manage some flight operations in both Bangladesh and India and I am going to spend sometime in both countries...so you should be hearing from me as SL2 and VU

42007. Millivac MV-828A RF millivolt meter

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-01 23:34:29 UTC

Topic: 42007 Message: 42007

What I have is a spare 'G' probe body with a broken plug. I can not find a pin out to rewire it. I have taken my good probe body and removed the plug but it is an older meter and the wire colors are not the same. Does anyone have the info? My wiring diagram does not show the colors on the plug and it is all pcb wired and I can not trace it.
I have one spare meter and the G probe body without the diode cartridge that I have no use for but would like to fix the plug before offering it to anyone who could use it. I do not wish to sell it but would give it to a needy ham, who may be able to use it, for just the mailing cost. You would need to find or make a diode cartridge for it. I would like to have the pin info for my notes even if you take the meter and probe as is. The 828A works fine for me although I do not know of anyone else who uses one. They can still be serviced by several places found on the internet. I would like to have a HP 410C but can not justify the cost since I have this 828 and a Fluke DMM. The Fluke is nice but the digital is a pain. So, is anyone familiar with the millivac?

You cannot substitute the HP-410C for your Millivac 828. I have a 410C and would not be without it but not for measuring RF voltages. For that I use my Boonton 92E or O-scope.

The HP-410C ac probes lowest rf (ac)range is .5v rms or 500 mv. It just doesnt go low enough. You cannot measure Hybrid TIF signal levels with it very accurately as it puts the readings very far down on left hand end of the meter scale. Your Millivac is much more sensitive and has a low range of 1 mv. It is better to have a 30 mv and/or 100 mv range to measure TIF signals which ranges from approx 15 mv to 40 mv depending on model of Hybrid.

I very seldom use the AC probe with my 410C. Its 100meg plus input impedance on DC voltage ranges allows you to directly measure AGC and ALC bus voltage. This is where it shines.

So I recommend you keep a functional and calibrated Millivac 828 and acquire a HP-410C if you are going to do much service work. If I had to keep only one it would be the Millivac or change to Boonton which seem to be plentiful.

Thanks Terry, I have the same manual but the schematic is so small I could not make much out of it. This copy will print out fairly larger than the one I have. I have looked for the schematic but could not find a better until now. I said I could not justify the cost of a good 410C since I have the Millivac and you have confirmed it. I also do not like good equipment lying around broke even tho I do not need it. I must fix this probe and I will take a look at the schematic over the weekend. I do like the millivac and I got a fairly good deal on the new one. The fellow said it did not work so he took 60 bucks for it. It did not work so I put my probe on it and viola. I took the old probe apart and the wires were twisted off. So, I gotta fix it. Just thought someone in the group could use it. Thanks for your kind attention and 73.

Yes $60 was a steal. I would like to have it but really dont need it as I have nice 92E so lets get it to someone who understands why they need it and will really use it.

Occasionally on ebay you find a Boonton probe going reasonably priced. Most likely could remove end connector and even hard wire to the Millivac if had too. I suspect diodes in Millivac, Boonton, and Ballantine are all very similar. They all use pair of series diodes in shunt and dc output feeds a chopper.

Here is schematic of the Boonton probe.

Thanks Terry, I got it. Must have been put up late yesterday. It was not there when I looked. At work right now and can not talk. Will get back to this later this afternoon. I checked the schematic out last nite but did not get it done. I can not tell where the wires go without looking inside the probe itself. Not as good at it as you. I will get it done tho.

Hi members;

I look for the pin connection datasheet of this above relay from a old Kenwood TS515
I have some contact failures on one of two of the same type of relays in this transceiver.
After measure both relays,they give the same failures on the same contacts !!!
Could not be possible that both have same failures on same contacts ?
But in extreamly case,it always could be possible (two broken relays at same time) ?

Thanks es regards Jean ON4AEF.

If you do not have the owners manual with Schematic can obtain it here on WB4HFN Rons website. I do not have a MH4P data sheet. The schematic will show you what functions the relay contacts perform. One relay is the Aux relay and it switches the AGC, the meter, RX/TX bias etc. The other relay is the Antenna T/R relay. After literally thousands of operations over all these years not unusual to have dirty or high resistance contacts.

Have you tried cleaning by pulling paper wetted with contact cleaner thru the contacts with light pressure applied to the armature? If this is not successful then go ahead and lightly burnish the contacts. You have nothing to lose at this point.

Substitute relays are available from Hybridrestore and Kens Electronics in Kalamazoo Michigan. These substitutes are NOS relays.

Okay, now for the happily ever after ending hybrid story...

I bought a 5-pack of new button covers from John, KF7QGU. Having struggled with re-insertion while swapping the originals around, it was clear to me that taking the faceplate off was worth the small effort as a means of not damaging the new ones.

I pulled off the originals, and plugged on the new replacements. Each went on with a very nice feeling "click." Perfect fit, perfect feel!

The faceplate went back on without a hint of clearance issues, and the new switch covers are awesome. Now the switches match the excellent condition of the rest of the radio. No fiddly-loose SEND button anymore.

Am hoping to check-in to the Hybrid net this afternoon (we'll have to see-it's prom night so who knows how the afternoon will play out...heh).

Thanks John KF7QGU for providing an excellent new source for these parts!

73,

Mark N8MH

I agree. Recently bought a set from John and installed on a TS-520. A little effort but allows you to clean all the knobs and front panel. Terry K9TW

I appreciate Mark's good comments. I also am using these replacement handles on my own two rigs and they look really sharp.

As some of you may know, I've had these on eBay and I think everyone familiar with eBay knows that there additional fees for ebay sales and use of Paypal.

I'd be happy to sell direct and not have to deal or charge back for Ebay/Paypal's piece of the action. I've gone even a bit lower on the pricing just to be price competitive.

Contact me if anyone is interested, though I think Mark got a set of five black, I can mix black and gray to match the original factory color configuration as needed.

Best wishes and '73's

John / KF7QGU

Know this is OT but maybe someone here can assist us.
your group was reccommended to us for a problem we're having.
Our ARC is helping with the estate of a SK member and we're stumped. There is a Kenwood TS-930SAT in it. It has a filter marked (either) 2H8 or 2H9 on the side (chrome, about 1.5" x 1/2" in size) (hard to tell the marking using a flashlight against the shiny metal. No other marking can be seen.
By any chance, could anyone tell us what the freq of it might be. We know it will be either for CW or SSB.

Tks in advance

Date: 2013-05-05 19:09:56 UTC
From: mvgilger
Topic: 42024 Message: 42024

The Saturday's net on 40 meter we had 12 stations checking with good band conditions. Out of the stations checking in, there was:

1 running TS-520(x)
1 running TS-530(x)
5 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 16 stations checking in under very poor band conditions. We had 4 new check-in, W5AMU, WA7ITZ, KL7IBY and WB7VNL.

Out of those, there was:

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 12, Sunday's total = 16 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

42025. Guidance on making a test probe for IM-18 VTVM?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-06 17:44:38 UTC
From: paul.nussbaum
Topic: 42025 Message: 42025

The IM-18 has arrived, but no test probe.

Looking around the internet I see some advising to use a pen body, others saying that won't stand high voltage, some saying use musical instrument cable, others warning the impedance will be incorrect unless it is RG58, some advising installing the megohm resistor inside the IM-18 case (!), others reminding that the resistor is properly positioned in the probe body so the lead does not load... apart from some remarks by Terry Wagoner here lately, I have not found instructions I trust.

I know from past experience that building something goes much better when I have experience with what I'm building. I have not used a VTVM or this kind of probe before so I don't know much of what to look out for in the build process.
Plug, cable, resistor, switch, body... the IM-18 document illustration of the exploded probe assembly is not clear to me. Pictures in other places show a separate lead with the alligator clip, but the exploded view does not indicate that... also not clear why the resistor leads make a "U" shaped bend in the body.

If someone knows a proper method on the internet that they could link, or if they would be so kind as to present a method here, or even if someone has a spare and would be happy to part with it, I would be very appreciative.

Thanks,
Paul
AD5FT

Topic: 42025 Message: 42026

Paul,

You can use small diameter PVC pipe with end caps available at your local hardware store, a screw with 2 nuts installed through and held securely in one end cap, then file the tip into a point, then use coax cable connect the tip to the VTVM 1/4" plug that plugs into the VTVM socket. The ground can be made from coax cable braid and an alligator clip. The 1Meg resistor in series with the probe's tip is necessary for measuring DC voltage. The switch simply bypasses the 1 meg resistor when measuring AC voltage (resistor is not required when measuring AC voltage). I do NOT recommend installing the 1 meg resistor inside the IM-18 as you may have read on the web. A SPDT slide switch can be used as the switch, simply follow the schematic wiring diagram that shows how the switch and resistor are connected to the probe cable's center conductor.

Before you attempt to use your VTVM, I highly recommend you spend some time reading theIM-18's manual's section on page 26 titled "Using Your VTVM". This section will help you understand how to use the IM-18, how to read the meter scales, and how to take simple learning measurement of resistance and voltage (AC and DC). Using a VTVM is not difficult.

Topic: 42027 Message: 42027

Has anyone seen a basic CAT interface function added to the 820s?

When I?m logging QSO, plugging in the frequency to the log program is a (small) hassle and I thought it would be cool if my logger could read the 820s frequency same as it does with my modern rigs.

I don?t think this would be very difficult if a guy uses a small uP and serial I/O. But I wondered given the popularity of the rig if anyone had done this in the past already?

Hi everybody
Have a question, a friend of mine just got ahold of a 520, he asked me to look over it, since I too have a 520..
Now, when AGC switch is turned on, fast or slow, nothing happens...
All other switches works fine, and all voltages on AVR board are correct.
Any ideas?
Rig is in good condx, only other thing, it's missing the cover on PA cage though...
Thanks in advance

Jeff,

This question has been asked numerous times over the years and the answer is "No".

You say it wouldn't be very difficult. I don't think you see the whole picture here Jeff. It's not as simple as you think it is! Circuits will have to be designed, built and thoroughly tested that sample power output, S meter, the operating frequency, band and any other feature you would like. Additional circuits have to be designed that communicate this information to and from the microprocessor, including the serial interface (USB or older RS-232). Firmware code has to be written and debugged that controls all functions including being able to understand any/all commands sent to the microprocessor from the computer's CAT software. This is NOT an easy and simple project to tackle!

Lars,

What did you expect to happen when the AGC switch is set to FAST or SLOW?

Mike,

Thanks for the comment. You are right, but that depends very greatly on how deluxe a guy wants to make it.

Let me give you a super simple example. You can read the frequency on transmit with the uP - and respond to a single cat interrogation providing the frequency and any dummy data to make the logger query not error out. Would not even need to get inside the rig to do that.

In my case, I only use the rig for CW so I could hard code the mode. But the next step from that would be to dig the mode out somehow. If you are willing to say that the modes are limited to SSB and CW, then I think you could probably guess that from reading a signal strength over time and assuming that with a high duty cycle, it’s CW, and with a low one, it’s SSB.

For me, that info (the TX freq) and a reply on the mode would be enough.

Subject: Re: [TS-520_820_530_830] Adding basic CAT frequency functionality to the 820?

Jeff,

This question has been asked numerous times over the years and the
answer is "No".

You say it wouldn't be very difficult. I don't think you see the whole
picture here Jeff. It's not as simple as you think it is! Circuits will
have to be designed, built and thoroughly tested that sample power
output, S meter, the operating frequency, band and any other feature you
would like. Additional circuits have to be designed that communicate
this information to and from the microprocessor, including the serial
interface (USB or older RS-232). Firmware code has to be written and
debugged that controls all functions including being able to understand
any/all commands sent to the microprocessor from the computer's CAT
software. This is NOT an easy and simple project to tackle!

Topic: 42034 Message: 42034

I'm thinking of selling my TS-820S Station, and was wondering what it might go for. Thought this might be the best place to find it's worth. I have the following:
TS-820S
SP-820
VFO-820
SM220 with pan adapter
MC-50
I have owned these since 1980. The radio just came back from AK4AA, did a restoration on it. Any help would be appreciated.

Thanks
KM5RV
Robert

42041. TS 520 CW Filter Switch

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-07 23:47:25 UTC
From: tfrugia81
Topic: 42041 Message: 42041

Hello Group,

I acquired a TS-520 yesterday as a project to restore (backup to my 520SE). It came with a CW filter, but of course no switch! I have searched the group and the web and found the most common way is to utilize the FIX CH switch, and I like that solution.

However, the mod says to 'bridge' FIX CH 4 to CW, and FIX CH 3 to SSB. That part makes sense, but where does the brown wire go (that usually attaches to CW)?

The only schematics I have handy (in a viewable format) are for the 520SE (the 520s schematics look to be the same for this section of the FIX CH board). Looking through that, it appears I should move the brown wire that's currently attached to CW over to the C pin on the FIX CH AVR board. Is this correct (using my VM it looks like it would do the trick)? I'd appreciate someone verifying this for me before I make the change. I'm still new at this stuff but I'm learning!

Thanks all, 73

42043. Using hex/allen keys on tuning slugs

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-08 13:05:15 UTC

Topic: 42043 Message: 42043

Hi all,

Good to meet everyone! I'm picking up a 520SE at weekend which looks in fine business condition. Looking forward to learning lots from people here.

Have the manual and it's good to see receiver alignment is straightforward with the calibration signal and coil board. I ordered a suitable plastic hex alignment tool to minimise danger of slugs cracking (I hope not too many already cracked...), but I was curious why there are so many warnings about using a metal allen wrench of the correct size?

Obviously metal would affect the inductance so be unsuitable as material on that score, but why would a metal rather than plastic allen wrench be more likely to crack the slug, if both are correct size?

Whichever material is softer will deform slightly relative to the other when you apply torque. With a plastic tool, it is the plastic which will deform so as to present more surface contact area to the planes of the slug slot giving a more even distribution pressure.
A metal tool will make less contact to the slug slot planes and will tend to try to deform the slug where it makes local contact - smaller area of surface contact means more local pressure on the slug slot planes to apply the same overall torque to the slug.
If the slug cracks, it will respond to either a plastic or metal tool by trying to expand in its housing when you try to rotate it, acting like a drum brake. Cracks are often invisible even under close inspection with a light and magnifying glass.

Also, many people have initiated an adventure in trouble shooting after releasing a metal tool into the chassis.

Greetings Group,

I totally agree with Terry. DO NOT GET METAL TUNING WANDS...etc...near "tuning slugs," as you will be very sorry...and then you post a question here, as to how to remove "stuck/broken" slugs. When getting a "new" radio/rig...I always take a very bright light and a magnifing lens and inspect all the tuning slugs...especially the 520/520s rigs...BEFORE I even attempt to adjust/tune them. IF you find broken/cracked slugs, mostly it is because a "previous owner" did what you may be thinking of doing...but has already done it...and now it's your problem. IF, you attempt to tune/adjust a tuning slug and it does not move...STOP...and investigate...In my short history of "fixing" these fine old rigs...I have found that applying a SMALL drop of non-petroleum based lube on the affected piece...and letting it sit for a bit...and then trying to turn it again...has yielded very good results. Petroleum based oils/lubes....will swell some of the plastic that the "cans" contain...and make it even more difficult...to turn/remove.

More than likely...I have opened a BIG can of worms as to this topic...but...it's (due to inflation) my 25cents worth

I see no reason why this should be a "can of worms", Joe. Pure and simple, two reasons allen keys should NOT be used. One, the metal will detune the circuit you are trying to tune, making the results unpredictable, and much more difficult to achieve the desirable ones. And Two, as has been mentioned, the likelyhood of breaking a slug is MUCH MORE possible.

Just DON'T DO IT !

Jim,

as per my "can of worms" comment...I was talking about using "non-petroleum based" oil/lube. Some swear
by WD-40...and other "lubes"...which I find totally contaminating and damaging to certain parts of these old gems.
That's why I usually do not mention any brands...except for DEOXIT

Topic: 42049 Message: 42049

Someone sent me an email about availability of an AC/DC probe for a Heath VTVM and I have mistakenly deleted it(of course it was a mistake, I would not have done it intentionally)Could that person be so kind as to Email me again? I promise I will not delete it until I answer it.

Adrian,

This is all good advice, from experience if you do have a slug that doesnt want to move, you can use a clean soldering iron and heat the slug and then turn the slug straight away, this usually breaks the seal and you can then go on your merry way tuning the radio.

Subject: [TS-520_820_530_830] Using hex/allen keys on tuning slugs

Hi all,

Good to meet everyone! I'm picking up a 520SE at weekend which looks in fine business condition. Looking forward to learning lots from people here.

Have the manual and it's good to see receiver alignment is straightforward with the calibration signal and coil board. I ordered a suitable plastic hex alignment tool to minimise danger of slugs cracking (I hope not too many already cracked...), but I was curious why there are so many warnings about using a metal allen wrench of the correct size?

Obviously metal would affect the inductance so be unsuitable as material on that score, but why would a metal rather than plastic allen wrench be more likely to crack the slug, if both are correct size?

42052. Erratic IP on TS-530S during tune up

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-08 21:33:05 UTC
From: Louis Wilen
Topic: 42052 Message: 42052

I have a TS-530S, original owner, never been serviced by anyone except myself, and the only service that I've done is occasional cleaning with compressed air, tightening PCB screws, and re-centering the RIT. Also changed the driver tube about 15 years ago.

During operation (except as explained below), everything works fine, acts fine, output power is about 120W CW, HV is 900V, idle IP is set correctly and is stable, and it checks out good on all tests that Ken (K4EAA) suggests in his "Tech question mailbag." For what it's worth, I checked the ESR of the large power supply capacitors and it was well under 1 ohm.

But it has one problem that has developed recently. During initial tune-up after power on, the IP jumps around erratically while adjusting the plate control. It dips but it jerks around, not a smooth dip. It settles down and acts normal after a keying and adjusting the plate control several times, and then the rig tunes up fine. If I tune up again on the same band or a different band, it tunes up fine without acting erratic. But if go away and come back another day, the erratic IP during tune up comes back.

Any ideas?

Louis

>

Barry,
I also have an 830.
With mine, I turn on filaments,
and then it outputs 1 W when cold and 3 W after 30 minutes of warmup.
Other controls function normally, similar to yours.
Have adjusted the "grid drive" on the back panel, for 60mA as the manual describes.

Wrote to
http://www.oldhamdave.com/
and Dave responded with a repair time frame of 10 weeks off.

Terry, K9TW,
I'm an old ham, set in my ways. I regularly use an HW-8 at 1 W QRP, on 20M, CW only. So, I am used to those things.
I also own an TS-830S Cadillac, and I agree it is "nice".
My 830 requires some repair, EPO is usually ONE Watt !!! and I am gathering insight into that repair process. I have stopped using the 830 over concerns of damaging something.

Question: Are you guys saying that the S2001A is a replacement for the 6146B originals ? Sounds like it.
Question:
Can I expect to run the 830 at 10 Watts or 40 Watts or 70 Watts, in the CW mode ?
Would setting the "grid drive" on the back panel achieve this lower power safely ?
Would running lesser power extend the life of the final tubes ?
I have contacted David LyndonTS-830 service David Lyndon, 85 Woody Farm Road, Hot Springs, NC 28743 off I-40 via http://www.oldhamdave.com/ Any comments on this?

So, Terry K9TW you sound like you have lots of the right kind of careful experience. I liked your response to another topic.

Louis:

When you set the resting plate current by adjusting the bias voltage pot on rear of rig is the plate current steady then?

Also, do you hear any arcing or frying sounds from the PA cage when the IP is jumping around?

You can measure and monitor the operating bias voltage and the Screen Grid voltage at the 6146 tube socket pins as you load the rig to make sure neither one of those voltages are moving around. Both should be stable key down.

Be very careful monitoring these voltage. Personal safety issue from inadvertent contact and dont want any arc or sparks.

If resting plate current is stable then bias pot is probably clean and not the problem. If operating bias and Screen grid voltages are stable then I would open up the PA cage and visually inspect the Plate choke and bypass capacitor at its base for signs of overheating/discoloration. While there I would clean the rotor shaft wiper contacts on both the tank capacitor and load capacitor with De-oxit and blow off residual with canned air.

Lastly could be a dirty contact on the 4PDT flat pack Aux relay on the IF board. I have not had much success cleaning this relay. I would suggest replacing it.

42060. Re: TS-830 Power Adjustments and Repair Process

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-09 01:50:13 UTC
From: Terry Wagoner
Topic: 42054 Message: 42060

1. I still see some rigs with S2001 finals, but I would not go out of my way to find any. I have never seen a data sheet for one. I usually run RCA 6146Bs when I can and/or Sylvania 6146W (JAN).

2. There is no "grid drive" on the rear panel. There is a bias voltage adjust pot on rear panel that allows you to set the resting or idle or quiescent (no signal) plate current. Adjusting this voltage to approx -60 vdc will result in a resting plate current of approx 60 ma. You are setting the operating class at AB1 when you do this. You would not vary the rf output power with this pot.

3. The way to get any power level you want including QRP level is to use a pot and 9vdc battery connected to the ALC jack on rear panel. There is a schematic in the Files section to show you how to build and install this very simple negative voltage power source. You adjust the pot to adjust the ALC control voltage that is applied to the TIF amp dual gate mosfet on the IF board. The TIF amp provides RF drive to the Transmit Mixer on the RF board.

4. Any time you run lower dc input power you have lower final plate current which means lower plate dissipation which means lower heat. So assuming you do not have long off resonance key down times or use high duty cycle modes in theory should get longer tube life. However I think this will be one of these anecdotal things as very hard to measure and quantify.

5. Are you saying your 830 currently only has 1 watt rf output? If so at what HV and IP levels?

Subject: [TS-520_820_530_830] Re: Erratic IP on TS-530S during tune up

Louis:

When you set the resting plate current by adjusting the bias voltage pot on rear of rig is the plate current steady then?

Yes, perfectly steady at 60 ma on CW or 50 ma on USB/LSB.

Also, do you hear any arcing or frying sounds from the PA cage when the IP is jumping around?

No arcing or frying sounds whatsoever. (I am familiar with what you are talking about, as I've heard those sounds from my transmatch when I try to load up too short of a wire on 160 M -- which is not something that I normally do.) By the way, I'm tuning up into a 50 ohm dummy load.

You can measure and monitor the operating bias voltage and the Screen Grid voltage at the 6146 tube socket pins as you load the rig to make sure neither one of those voltages are moving around. Both should be stable key down.

Be very careful monitoring these voltage. Personal safety issue from inadvertent contact and dont want any arc or sparks.

I'll check that out if the deoxit fix that you suggest below doesn't cure the problem. I have the right equipment to measure these voltages, but I avoid that area whenever possible.

If resting plate current is stable then bias pot is probably clean and not the problem. If operating bias and Screen grid voltages are stable then I would open up the PA cage and visually inspect the Plate choke and bypass capacitor at its base for signs of overheating/discoloration. While there I would clean the rotor shaft wiper contacts on both the tank capacitor and load capacitor with De-oxit and blow off residual with canned air.

The Plate choke and bypass capacitor look like new. I'll clean the rotor shaft wiper contacts and load cap as your suggested.

Lastly could be a dirty contact on the 4PDT flat pack Aux relay on the IF board. I have not had much success cleaning this relay. I would suggest replacing it.

Thanks for the tips. Actually, I think that I'll try a different dummy load, too. It's the dummy load built into an ancient MFJ-949B tuner. Might as well eliminate that as a possible cause of the problem.

Yes I did not say anything about the external load coming and going.

Good idea to check dummy load and any coax jumpers PL-259 connectors from rig to dummy load (any cable/connection combination from rig to the dummy load). Do that before anything in the rig. On rare occasions the lead at the SO-239 inside the pa cage can have a poor solder connection. Also the Antenna T/R relay NO contacts could be dirty.

Should have told you to look at external load stuff first. Pulled the trigger too quick. Sorry about that.

For what it's worth, I checked the ESR of the large power supply capacitors and it was well under 1 ohm.
> >
> > But it has one problem that has developed recently. During initial tune-up after power

on, the IP jumps around erratically while adjusting the plate control. It dips but it jerks around, not a smooth dip. It settles down and acts normal after a keying and adjusting the plate control several times, and then the rig tunes up fine. If I tune up again on the same band or a different band, it tunes up fine without acting erratic. But if go away and come back another day, the erratic IP during tune up comes back.

Dave:

You are far too kind. I am going to have to send you a discount coupon!

I do not repair the VFO-230. Have had the covers off sum total of one. Didnt see any tubes/valves! Never took the time to sit down and figure out how they work.

If anyone is interested in hybrid repair can contact me off list for my repair policy and rates. I have a TS520 on bench about complete and nothing in the que. I no longer just do repairs. Only will do repairs followed by alignment. Will no longer accept hacked radios.

Might try Jim at HybridRestore. Also could try Old Dave or Cliff Holland. I have no personal knowledge or experience with either of these two gentlemen.

42065. TX Level Testing - Level Diagram questions

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-09 23:17:13 UTC
From: paul.nussbaum
Topic: 42065 Message: 42065

I am preparing to run TX level tests on my TS-820S. I have some questions about the level diagram:

1] MIC TP2

I'm not clear what "MIC" means here because the MODE for TX level testing is specified to be set to CW.

Is TP2 measuring the audio amp transistors without an audio signal present? I find TP2 on the IF board and looks like it is between the audio amp stages and the ring mod.

2] "These levels are measured at 14.175MHz"

Which "these levels"? Is it indicating the "DC voltage at reception" levels and/or all subsequent levels in the diagram?

If referring to the "DC voltage at reception" levels", how does one measure the other bands at 14.175? Is it just calling for the MIC control to be set to measure .25V at 14.175 as reference and confirm the other values for the other frequency selections at that setting?

Or is it indicating the expected values measured there for each band selection with MIC at full CCW?

Or is "MIC" just referring to the IF board pin called "MIC"? Nothing to do with the microphone input, the MIC knob, just indicating the entry into the IF board in front of the audio stage?

3] CAR Level 0.88V

I'm guessing this is a "setting" to establish the expected subsequent measures?
Is it calling to turn the CAR control to get a measure of .88V here?
Does this mean all my questions about "MIC" don't make sense? That would be a relief if it was clear to me what is supposed to be going on when measuring TP2.

That's what's confusing me so far; the rest looks straight forward, but we shall see... looking forward to it.

Paul

42066. Re: TX Level Testing - Level Diagram questions

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-10 03:36:59 UTC
From: Terry Wagoner
Topic: 42065 Message: 42066

" Mic TP2" is TP2 on the IF board. It is the output of the microphone amp and one of two input signals required for the Balanced Modulator to produce a DSBSC signal (double side band suppressed carrier signal). Unfortunately Mic amp and mic gain pot have nothing to do with TX Level Diagrams.

Yes TX Level Diagrams are run in CW mode so there will be no mic input. Like so many things in the TS820 Service Manual it is flawed. Just ignore it and ignore the Dc voltage levels at "reception".

Yes you do need the other input signal to the Balanced modulator and that will be the Carrier Oscillator output of Q17 which will be approx .88v. This level will be there if you have properly adjusted the output level from the Carrier Osc board at CA2 to approx 300mv. The service manual says 50 mv so ignore that. Some say they meant 500 mv and that is wrong and not achievable.

The other thing you need is the Car Level Pot advanced to provide a DC voltage to turn on ring diodes to produce a carrier at the output of the Balanced Modulator.

Here is how you run TX Level Diagrams:
1. If you have rf drive and can load the rig go ahead and load normally in CW mode into a dummy load to approx 100 watts output on 14.275 mhz. If 14.275 is a problem can run first pass on 7.200 mhz to get a feel for the test. Then repeat on 14.175 to see where level is low or missing.

2. If you cannot load to full rf output then just peak the Drive control on receiver background noise or use the Marker signal. Set the Car Level Pot to at least 1200. Ok to just set it full CW if unsure.

3. Leave heaters on and turn off the SG switch

4. Start measuring RF drive levels at the output of the TIF amp Q1 at Diode D44 on the IF board. Easier access than the molex connector.

5. Connect your rf probe ground lead as close as possible to the point you are going to touch probe tip. Usually just get it to nearby chassis ground will be good enough.

6. Flip to Send and touch or connect probe tip with a short mini grabber test lead to Diode D44. Should read approx 250 mv rms. Note:If using a single germanium diode probe may have very little or no VTVM meter indication as the diode barrier junction voltage will be around .250v. It is better to use RF millivolt meter or O-scope to measure TIF signal level. If using O-scope will read approx 700mv peak to peak assuming scope has sufficient bandwidth.

7. Unkey rig and move RF probe to RF Board Conn RF-1 Pin 10.

8. Flip to Send and should read approx 38mv rms. Same note as above cant read this level with standard germanium diode probe. O-scope will read approx 106 mv peak to peak.

9. Unkey rig and move RF probe to RF Board at output of Transmit Mixer Q1/Q8 at MD terminal.

10. Flip to Send and should read approx 1.5 rms volts. This is first place you will read actual transmit output frequency. If you obtain a very high reading here (3.0 rms volts or more) it indicates that the Mixer is not seeing the tuned circuits which are switched in by the bandswitch (bad bandswitch contact is common problem) or not seeing the control grid input of the driver tube. Could be due to bad solder connection at driver tube socket.

11. Unkey the rig and move RF probe to the plate of the Driver tube at DP terminal. Caution: High DC anode voltage here. If using homemade RF probe make sure the input coupling cap has minimum of 500 wvdc rating.

12. Flip to Send and should read approx 65 rms volts. Caution: DO NOT USE single germanium point contact diode RF probe here as the levels will exceed the PIV of the diode. PIV will be approx 2.8 times the rf voltage or approx 182 volts. Single 1N34A can handle approx 50 to 60 piv. Need 3 diode probe or Rf millivolt meter or O-scope. If using O-scope reading will be approx 182 volts peak to peak if you have scope with sufficient bandwidth.

13. Unkey the rig and move RF probe to the control grids Pin 5 of the 6146 finals tube socket.

14. Flip to send and should read approx 47 rms volts. Again do not use single diode probe as PIV will be approx 131 volts.

15. Unkey the rig and evaluate your as found levels. Of course if you have low or missing RF drive levels prior to the grids of the 6146 finals you will have aborted the testing and would commence troubleshooting the stage where drive levels are first noted to be low or missing.

Now there is another trick you can try if you are limited to a single diode probe and that is to reduce the Car Level Pot which will lower the RF drive levels. Have to be careful with this and make sure you have set drive levels below PIV of your particular diode. Will have to scale the results you get due to the reduced TIF level.

Many years ago I had to do this when I built and ran Heath gear and has only fundamental test gear.

I have a TS-820 here and my original 309c probe and IM-18 so could help you figure out a Car Pot Level that will allow you to measure Plate of driver tube and grids of finals if you need that.

You should be able to read the output of the Transmit Mixer at MD no problem and if it is approx 1.5 rms volt then you know all preceeding stages are working properly.

Paul:

First, let me say I am indebted to Terry for explaining the level diagram. I tried to use it some years ago when I was troubleshooting my TS-820S and did not get very far.

Also, the FIRST thing to do is what Terry describes relative to the carrier unit. And that incluces making sure it is on the right frequencies as well as producing a high enough output signal. This is not only because it is important but also because problems in terms of output and frequency are very common with 820's that have not been aligned and adjusted in a while.

But I would like to know what you are really trying to do? I presume you are not trying to read those various levels because it is fun.

What I would do, after making sure the carrier module is properly adjusted and all connectors are properly seated, is to measure the SSB transmit output of the IF board, all the way in the back, where that shielded wire comes out to go to the RF Driver board. The best way to do this is with an oscilloscope, and since you are only talking about 8MHZ a pretty modest scope with do the job.

Measure the output in both the USB and LSB modes. It should be a complex waveform with significant amplitude.

In my case I was trying to figure out why my TS-820S would only produce USB, with no LSB. This test showed me that the USB signal was fine and the LSB one missing. Checking the input to the SSB filter showed a signal, so the LSB side of the filter was bad.

That was not the only thing wrong with my TS-820S, but simply measuring the transmit IF board output told me a great deal.

Good luck!

Robert

Topic: 42065 Message: 42068

Robert/Paul:

The only time you should need to measure the output levels of the Xtal filter is if your TIF level at IF board is low or missing. In my experience this is not very frequent. Almost all low or no RF output occurs due to problems on the RF board. This is especially true if you have band specific rf output problems. The Xtal filter and Carrier Osc do not know what band you are on.

Robert is correct O-scope will be needed if you want to look at rf voltage levels at the output of Balanced Mod or input/output of the Xtal filter. Same for TIF as I previously mentioned. Fortunately a bad Xtal filter is rare and seldom reason for low or no RF output, but certainly possible as in Roberts case.

Keep in mind it depends on what you are trying to do. If you are trying to take and record accurate base line readings for future you need to understand the voltage limitations of O-scope bandwidth. If you are just interested in relative readings or comparing output of Xtal filter on LSB vs USB then a common 20 mhz BW scope will be just fine.

For accurate readings a 20 mhz BW scope measuring 8.830mhz will read peak to peak (P-P) voltages approx 7% low. So at output of Xtal filter instead of approx 55mv P-P you will read approx 50mv P-P. At 14.175 the readings will be approx 15% low and at 20mhz will be -3dB low or only 70.7% of the actual voltage level. This is why it is always best to buy a scope with as much bandwidth as you can afford. Most all of us started with 15mhz to 20mhz BW or less scope and progressed as we got more serious about troubleshooting. For Kenwood work a 100mhz is good and a 200mhz to 250mhz (like a Tek475/475A) is just about right.

Of course if your scope is out of cal readings can be even lower than the affect of BW limitation. As long as you understand this you will not be confused or think that you have bad readings. I have a point paper and a calibration chart if you are interested. All of this is available in Tektronix O-scope Primers on the web.

42069. ALC Circuit for TS-830

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-10 12:29:00 UTC
From: bnorman37
Topic: 42069 Message: 42069

Greetings to the group! I was wondering if anyone has used the ALC circuit that is posted in the 'files" section to reduce power out?? I have an amp with a lot of headroom and have to turn the mic gain very low. It makes more sense to me to use the ALC to reduce drive power and then I can adjust mic gain to a normal level. Thanks in advance for your replies....Barry KF4WGR

42070. Re: TX Level Testing - Level Diagram questions

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-10 16:10:46 UTC
From: paul.nussbaum
Topic: 42065 Message: 42070

Terry, Thanks for the help. Sounds like I will need to build an RF probe. I don't have a scope.

(Robert, the reason I'm doing this is to trouble shoot a problem - I'm not getting an indication of ALC level during tune up and if I tune up in CW mode the output is just a few watts. This problem appeared suddenly while I was aligning the coils - before that everything was fine, good ALC, strong power output.)

I see plans using 1N34A diode, 4.7Mohm resistor, and 0.01uF capacitor for VTVMs with Zin 11Meg like the IM-18.

Putting three diodes in parallel, they will each still see the same voltage right? I don't need to add a switch to take them out when measuring low levels?

Does the rf probe need to be an independent self contained probe or can it be an "extension" to the combined AC/DC multi-probe?
If so, do I need to alter the rf probe resistor value or make other adjustments?

Thanks,
Paul

Paul:

I am sure I previously told you that you will need to buy or make two RF probes for Kenwood work. Probably lost in all the details? Neither of which will allow you to measure the TIF signal level or Balanced Mod output or output from your Xtal filters. As I said most cases of low or missing RF output and no ALC indication are not due to missing or low TIF, but it is certainly possible.

Here are some TIF RF voltage readings for a good 100 watt TS-820 with ability to peg the ALC indication full scale with Car Level Pot advanced to approx #2 to #3 position. These are taken at the IF board at molex Conn IF 3 Pin 2 TIF at 14.175mhz in CW mode with SG off.

When you first connect a RF millivolt meter or O-scope you will see a signal. With a single germanium diode rf probe you may see slight deflection on the 1.5vdc range of your IM-18 VTVM. This is the 23 Mhz VCO signal coupling back from the RF board. It is approx 18mv rms level.

As Robert told you the TIF signal is a complex waveform due to the presence of the 8.830 carrier and 23mhz VCO signal and if not familiar with O-scope triggering can present a problem.

Not a problem if using a RF Millivolt meter.

Flip to Send TIF voltages:
Boonton 92E = 48 rms rf volts
Heath 309C RF probe (1 diode) = approx 0.10 to 0.20 rms volts
Heath PK-3 RF probe (3 diodes) = may see very slight meter flick
Rigol 100 Mhz O-scope = 48 rms volts (with 10x low capacity probe and no 50 ohm terminator)

ROBERT: Please pass your TIF level readings on to Paul.

Paul: No the diodes in a 3 diode probe are not in parallel. They need to be in series to measure the high peak level at Driver tube plate and Finals control grids. I will post a separate RF probe primer as this thread will get too long and cause heartburn.

> >
> > Keep in mind it depends on what you are trying to do. If you are trying to take and record accurate base line readings for future you need to understand the voltage limitations of O-scope bandwidth. If you are just interested in relative readings or comparing output of Xtal filter on LSB vs USB then a common 20 mhz BW scope will be just fine.
> >
> > For accurate readings a 20 mhz BW scope measuring 8.830mhz will read peak to peak (P-P) voltages approx 7% low. So at output of Xtal filter instead of approx 55mv P-P you will read approx 50mv P-P. At 14.175 the readings will be approx 15% low and at 20mhz will be -3dB low or only 70.7% of the actual voltage level. This is why it is always best to buy a scope with as much bandwidth as you can afford. Most all of us started with 15mhz to 20mhz BW or less scope and progressed as we got more serious about troubleshooting. For Kenwood work a 100mhz is good and a 200mhz to 250mhz (like a Tek475/475A) is just about right.
> >
> > Of course if your scope is out of cal readings can be even lower than the affect of BW limitation. As long as you understand this you will not be confused or think that you have bad readings. I have a point paper and a calibration chart if you are interested. All of this is available in Tektronix O-scope Primers on the web.

42072. RF Probe Primer

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Paul:

Here is RF probe primer. Suggest you look on web and start with N5ESE classic probe. Also, if you do not own a ARRL Handbook it is a must. I would get a mid to late 70s version. The Test & Measuring Chapters will explain RF probe construction and use.

You will make or buy a probe(s) that takes the place of your Heath AC/DC probe. It will have a 1/4 phone plug on it and be plugged into your IM-18 VTVM and you will set the Range switch to 1.5volt DC minus.

Any diode will rectify RF but not any diode will make a good RF probe. It depends on what you are trying to measure. In the Kenwoods you need to be able to measure and adjust things like Carrier Oscillator level, Hetrodyne Oscillator level, VCO level. You will use a single diode probe for these. You will also want to measure RF drive levels at the 12BY7A Driver tube plate and 6146 final control grids. You will use a probe that has 3 diodes in series for this application.

The best diode for these probes is a germanium point contact signal diode that has low forward voltage and high reverse voltage. A germanium signal diode will have a barrier junction of approx .250 volts. It will read lower than this, but not accurately.

Good diodes include:
1N34A
1N270
OA91

The maximum rf voltage you will want to measure with these diodes is approx 30 to 35 rms volts. Heath always recommended no more than 30 volts.

You can also use a Schottky like a 1N5711 which will have flatter freqency response, but will not be as sensitive as they have approx 0.400 forward voltage.

Some say OK to use a 1N914 or 1N4148 fast switcher. DO NOT do this. These are silicon diodes with 0.6 to 0.7 barrier voltage.

You can build very simple probe with a series diode, but I do not recommend that as the probe then is fooled by the offset voltage of its junction. A better design is like Heath or N5ESE that uses a shunt diode. The probes will read negative voltage. This is no problem for your IM-18 VTVM.

Now this is important: Remember the diode is seeing the peak of the rf voltage you are trying to measure so the reverse voltage will be approx 2 times that voltage level. So when measuring the approx 65 rf rms drive level at plate of 12BY7A the diode must be able to withstand approx 65 X 2.83 = 184 reverse volts! This is why you cannot use a single diode probe. You will burn it out. The germanium signal diodes I have listed have a peak reverse voltage rating from approx 50 to 100 vdc. You should pull up the data sheets and look at the specs before you use any diode. Placing 3 diodes in series for your second probe

ensures that you wont blow it up. Just have to realize that this probe will have a barrier of approx .9vdc so it cannot be used for low level testing. Just make sure you clearly label each probe so you dont reach for the wrong one. You wont hurt the 3 diode probe, but can hurt the 1 diode in an instant.

The resistors in these probes are selected to ensure proper scaling with your 11meg ohm VTVM. If you use a DMM may want to change value for 10meg input for best accuracy.

Make sure that you use a blocking/coupling cap that has a minimum WVDC of 500 volts as you will be touching this probe to the plate of the 12BY7A which has over 300vdc on it.

Heath used a 1N191 diodes in their probes. It is a gold bond point contact diode and no longer available. Can find them on Ebay but go for a premium around $5.00 each! Nice diode but not necessary.

By the way an old single edge razor blade and a safety pin with a piece of pencil lead makes a fine point contact signal diode. Ok for your crystal radio, but a little hard to package in your RF probe!

Paul: There is a Heath 309C and 337 probe listed on Ebay right now. The nice thing about these probes is you get a very nice tube/body and probe tip. The 309C is a single diode ready to go. The 337 is a Demodulator probe that would be easy to re-configure to a RF probe and install a 1/4 phone plug instead of the spade lugs. Something to think about. Not as much fun as building your own, but depending on what kind of junk box you have may be just about as cheap to buy the Heath probes?

Might also give WB2KNR Jimmy Lamanteer an email and see if he has any extra Heath probes. He has upgraded to Boonton RF millivolt meters and may have Heath probes he is willing to sell?

Terry K9TW

Paul:

Low power and no ALC after a session of adjusting coils says one thing to me: Bad 12BY7A.

I once killed a good strong used 12BY7A in the space of about an hour as a result of doing lots of transmits during adjustments.

Good luck!

Robert

> Greetings to the group! I was wondering if anyone has used the ALC circuit that is posted in the 'files" section to reduce power out?? I have an amp with a lot of headroom and have to turn the mic gain very low. It makes more sense to me to use the ALC to reduce drive power and then I can adjust mic gain to a normal level. Thanks in advance for your replies....Barry KF4WGR
>

Yes i use the alc to reduce power. It works but take in considerations the over shoots. You will find that at very first syllab there will be a spike at full power. Easily to be seen by an oscilloscope or on a true peack wattmeter.

It depends upon your Amp it this a problem or not.

Paul: I was under impression you tried another driver tube?

If not, Roberts advice is spot on. Always reach for the simple "experiential" stuff first like molex connectors, tubes, relay contacts etc.

The 12BY7A runs class A and runs at its max plate current and gets pretty hot. Normally you can do a lot of key down testing/tuning without hurting it, but if you have loss of RF drive and ALC indication on all bands after peaking the Drive and Mix coils on just one band reaching for another 12BY7A is a good first step as Robert suggests.

If you did try another 12BY7A and no improvement then running TX Level Diagram will pinpoint where you are losing RF drive in a matter of minutes. Finding out what is wrong at that stage will take a little longer. Need to make sure you have the necessary "goes ins" and "goes outs" and if you have them then need to take CBE and/or DSG dc voltages at the involved active device.

If you are building a modest Kenwood service bench you have a good start with the IM-18 VTVM. As you know you need the rf probes to complement it. After that I would add a Frequency Counter and a RF Signal Generator. A LC type RF Sig Gen is OK to start with as it allows signal injection testing. Not good for alignment because they lack calibrated output level. After those key 3 pieces of test gear I would add a Scope and a 20 mhz BW unit will be ok to start. An Audio or Function generator is also nice for troubleshooting the Audio output and Speech amps and driving rig for TX LSB/USB Carrier osc adjustments. With Lap-top PC in the shack today you can download free tone generator software and use your sound card for audio work.

Barry,Joe, et al,
I use a 150K pot in the screen grid voltage line to the 12BY7A. I run a 811A amp and use 50-70 watts drive from my 830S. A much simpler mod to install and/or remove. It works fine on my 811A and I notice no irregularity with a bird 43P meter. I can run normal input from the 830 with no adjustment to mic gain. Works as tho no amp was in line and signal reports are good with no distortion reported. Worth consideration. It just seemed simpler to me.

P.S. I experimented with my test rig first (TS-530 and it takes a lot of abuse, bless it's heart) Not much that could go wrong with this mod but you just never know.

I have a Heath VTVM model IM-5218. I think it is from 1979 and it has a pair of solid state tube replacements instead of the 6AL5 and the12AU7.

More relevant to this discussion, there is an unmarked RF probe, but the instruction sheet calls it a "PKW-3" and it has 3, 1N191 diodes. The specs say that it is good to 90V RF, 1khz-100MHZ, and 1000VDC.

You might want to look for one of these for HV measurements.

Subject: [TS-520_820_530_830] Heath RF Probes on Ebay

Paul: There is a Heath 309C and 337 probe listed on Ebay right now. The nice thing about these probes is you get a very nice tube/body and probe tip. The 309C is a single diode ready to go. The 337 is a Demodulator probe that would be easy to re-configure to a RF probe and install a 1/4 phone plug instead of the spade lugs. Something to think about. Not as much fun as building your own, but depending on what kind of junk box you have may be just about as cheap to buy the Heath probes?

Might also give WB2KNR Jimmy Lamanteer an email and see if he has any extra Heath probes. He has upgraded to Boonton RF millivolt meters and may have Heath probes he is willing to sell?

Hi Don:

I have always wished Kenwood would have copied the old boat anchor radios of the 60s and 70s like the Heathkit DX-100B and TX-1 Apache and others. They had two front panel driver controls. The same air variable like Kenwoods to tune driver tuned circuit to resonance and a 25K 4 watt pot in series in the 5763 driver tube screen grid supply that controlled the amount of output power from the driver tube by varying screen grid voltage as you are doing.

Of course no room on the Kenwood front panel unless you used a concentric pot and I still dont know where it would go. Heath did have problems with their pot and I think the wattage rating was too low as I recall. I remember having to replace one in my Apache.

I have thought about mounting a driver tube SG pot on rear panel of my TS-830, but hate to drill holes in any of my rigs.

Today a much simpler and easier mod is to install a T-pad Attenuator in the coax jumper between the TS-830 and the Linear Amp. No need to remove rig covers or make any wiring changes. T-pad attenuators are very easy and cheap to make using Caddock Thick Film Resistors. These are readily available from Mouser.

For a 2dB attenuator pad that will result in approx 65 watts output you need two 5 ohm 30 watt resistors and one 200 ohm resistor and a bud box to mount them in. Can use a slide switch to by pass them or get fancy and use a relay to by pass them.

For a 3dB attenuator pad that will result in approx 50 watts output need two 10 ohm 30 watt resistors and one 150 ohm resistor.

It doesnt get much easier than this and you have not modified your hybrid.

Hello Terry,

Thanks for the reminder. I had recently aquired this 811A amp from a ham buddy. I have never used an amp but the guys talked me into it after they heard enough of my complaining about getting cut out of good CW DX contacts in pile ups. You know how frustrating that is after waiting patiently for an oppertunity and unkeying and hearing a needle bending signal who evidently put me out of contact. Anyway, I got the amp and for the last month have been trying to figure a way to tone the exciter down without detuning. When I saw your post a week or so ago I remembered all about the old days When we used real boatanchors. Anyway I got to work on a couple experiments and I am convinced it is the best way to go. I used an existing hole in the rear panel and rerouted the 210A line. I am still searching Mouser for a more suitable pot. I pulled some from my junk box but they are not stout enough for my taste. I did have an old 250K pot from some old Kenwood so I put that in my trusty experimental rig and It works fine down to no out put. I think I am going to have to spend some real money for the correct part. I did not realize how much they cost nowadays. Now you come up with an idea that is worth pursuing. I usually keep this stuff on file and I love to build so I will give it some attention during this summer when it is to hot to go outside here in Mississippi. I am a hobbiest and I do love this hobby. Thanks for being here. I have learned a great deal more from just reading.
73, Don K5HFG PS Sorry for the long post. It is what it is. I will let you know how I fare with this project.

The DRIVE control on rigs like the Apache or DX-100 series was designed
to set the proper grid current for the final tubes to achieve proper
operating parameters. It was not designed to control output power.
Adjusting grid drive to a lower value just results in distortion to the
AM signal; too much grid drive results in premature failure of the final
tubes. On many boatanchor rigs, pad attenuators are still used to drop
power when driving a linear amplifier.

Yes Pete you are correct it was not intended to be used to reduce output power. My mistake. Should not go by 40 year ago memory.

I agree with use of pad attenuator. Could never afford a Bird or Weinchel or Collins. The new thick film resistors make it easy and affordable. Although some would balk at $10 for a resistor.

Will get all kinds of opinions about use of ALC with amps. Strong opinions on both sides. I know if you reduce power too low say around 10 watts it is possible to get 100 watts spikes on first syllables and first cw character. Some recommend not reducing output power below about 50%. I guess it depends on your exciter.

Some are proponents of using Audio Peak Limiter in the exciter mic line. I think common in broadcast studios but not so much for ham applications?

Some dont like the T-pad attenuator if the RX signal has to pass thru it. I think Kenwoods are hot enough that it is not a problem, but easy to key a relay to jumper out the attenuator in RX mode. I suppose at VHF could be measurable difference.

Thanks for keeping me straight. I do remember those cautions about not exceeding grid drive in the old Class C grid leak bias days. Fun times.

Good Morning All,

Have been reading up on the Attenuator Pads. I do not wish to buy a commercial device so I am going to build my own (more fun). Since I am not sure how much attenuation I need and I am using fixed value components, I may go the deluxe route and build a multiple pad with selector switch. That should keep me busy for the summer. I will have to get a part time job to pay for all the resistors. As I told Terry, I have received good reports with the drive reducer but do not have a Oscope so I can not tell anything as far as wave form but the P-P signal does not seem to spike. I have only reduced voltage slightly for 70 watts out of exciter. I have found a quick calculator on the web so that makes it easy to come up with some starting values. So, I am off to church. Will start with this project planning this afternoon. Thanks for the advice and opinions. 73, Don K5HFG

Yes Don it would be good to have a spectrum analyzer to evaluate the affects of various methods used to reduce rf output.

Kenwood ALC does it by varying the DC control voltage applied back at the TIF amp dual gate mosfet on the IF board. This results in lower rf drive being applied to the Transmit Mixer on the RF board which in turn lowers the rf drive applied to the Driver tube control grid.

Linearity is not degraded via this method and normal 2:1 to 3:1 average to peak power ratio is maintained with modulation. So talk power remains good and no splatter. It is always best to first load Kenwood finals to full RF output within max plate current limits and then reduce RF output by reducing rf drive at a very early stage. That is what using the 9v battery and pot applied to ALC jack does.

I suspect that if you are loading rig to full 100 watts out and then reducing Driver tube screen grid voltage to get your 60 to 70 watts you are probably OK but dont know that for sure without looking at it on spectrum analyzer. Absent that you can ask the boys running L-pan displays to take a look at your on air signal for you.

Here is a place to start studying T-pad attenuators. Phil Salas is a good engineer. I have purchased some of the units he builds and they are first class. Make sure you read to the end of his article.

Terry,

You mentioned Caddock Thick Film Resistors. I had not heard of this product until now.

Are these really what they appear to be? A 100 Watt, 50 ohm resistor for about $10 in quantity 1 ?

http://www.mouser.com/ProductDetail/Caddock/MP9100-500-1/?qs=YqNA2qefETASdLVDRoPxoQ==

Seems that by adding a heat sink and the appropriate RF connector, it would be easy to make an inexpensive dummy load. Am I on the right path here?

Thanks for the heads up article. Looks like I am probly spiking and just do not have the proper equipment to see it. I think Phil's pad is what I need to work on. I like his idea of cascading several in the box, maybe 1,2and 3dB using a rotary switch. I am wary of sliding switches with RF. Just a throwback to the old days. I have set my mind to it and it will be a good learning experience. Will let all know the outcome. My old experimental 530 will be glad to hear I am not going to put her thru any more of this.

42089. KENWOOD HYBRID USER NET (May 12th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-12 19:08:49 UTC
From: mvgilger
Topic: 42089 Message: 42089

This coming weekend is Dayton Hamvention. I'll be unavailable Saturday to host the net because of this. The Sunday net will be unaffected.

The Saturday's net on 40 meter had 17 stations checking in with good band conditions. Out of the stations checking in, there was:

4 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
2 running TS-830S

We had 7 new check-ins, VE3SHA, NY3R, K3CA, N4YNM, K3YUB, VE3BJR, and KB0CIG.

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 19 stations checking in under very poor band conditions. We had 10 new check-in, AF5IB, KI6LQL, AD5ZO, VE4ZZ, KC0ZRV, KD0PQX, W3UWH, KE5APY, KB5T, and WA6EFT.

Out of those, there was:

2 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 29, Sunday's total = 35(Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Yes you can make dummy loads or attenuators with them. They look like a audio power transistor with mounting hole, but only two leads on them. Here is an example. I have a commercial CelWave 250 watt dummy load at my bench that is built just like this one.

http://www.n0ss.net/dl_30w_hf-uhf.pdf

G'DAY C.A.

In I use to have this problem not just with Hybird radios but all my radios, the fix I found was to have antenna siwtched to ground or disconnected when radio not in use so when turning radio on there was FSD of meter, then I switch antenna to radio on. A few of my friends have high end inline static\lightening protectors and they dont have this issue. It costs nothing to try and lots to gain. I also make it a habit of disconnecting antennas from radios when finished in the shack.

Subject: [TS-520_820_530_830] TS 530SP

I recently purchased a mint 530SP. Sometimes when I turn on power, the meter needle will peg out and will take a second or so to drop back to normal, other times it only comes up to what ever the signal or noise level is. Suggestions?

Thanks,
C A

CA: It is normal for all Kenwood hybrids to have the S-meter peg hard full scale on power on. However, it should not stay there for extended time. If it is doing that come back for more help.

Here is why it is normal:

1. First how does the S-meter work? The S-meter is a FET based voltmeter that is monitoring your AGC bus line. The AGC bus is fed by 3.6vdc RF-1 reference voltage from the 9vdc regulator. With 3.6vdc on the bus the S-meter will read 0. Any lower voltage on the AGC bus will cause the meter to read up scale. When you receive an off air signal the AGC detector diodes turn on the AGC amp which pulls the AGC bus voltage down. The S-meter is reverse reading and when the FET sees the AGC bus voltage go down it drives the meter up scale. Same thing happens when you turn the RF gain pot CCW. You are lowering the AGC bus voltage and the FET meter sees this and drives the meter up scale.

2. So when the your radio is first turned on the AGC bus line is dead ie there is zero voltage on it. The Meter FET sees this and drives the meter full scale. The reason it slowly comes off the peg and back to zero is because it is charging the AGC bus timing capacitors that have discharged when rig was powered down.

3. The other thing that compounds it is that when you first turn on you will have off air signals immediately applied to the RF and IF amp chain and the AGC detector diodes will see this and quickly turn on the AGC amp and it presents a low Z load to the bus and pulls the AGC voltage down.

4. So you have dead AGC bus coming up to voltage and off air signals pulling it down ocuring at the same time.

5. It is best to leave your Antenna Switch to the ground or dummy load position with rig down powered. This should limit the S-meter upscale travel significantly with initial turn on. You will get some up scale deflection and slow decay, but greatly reduced. Try this and see if it improves.

Tnx for your response Dave. I suspicioned possible static electricity discharge from the antenna. Just moved shack into the house from storage bldg. Just about finished. Will connect coax switch so I can ground antenna this week. Again tnx for response.

Terry, thanks so much for a wealth of info. I've just moved the rig into the house and am in process of tying the last knots. Running a Windom cut for 14.332 with twinlead coming directly into tuner. This week going to change feedline to ladder line. Will install so can ground antenna when not in use. Tnx again for your input....

Hello all.
My approach to avoid this since I bought my TS 530 SP brand new in 1987 is as follows:
Always after turning it off I switch the AGC to -OFF-.
I became acostumed to do this from the very beginning.
So everytime I switch the radio on, I leave the AGC turned OFF so the S meter needle stays at its rest position.
Once the rig is turned on, you can switch the AGC to FAST or to SLOW and you¨ll see the needle doesn´t pegs to the right.
Hope this helps.

Don, it does not hang with AGC in fast position. Immediately goes back to the left in a split second. The strange thing is that it doesn't peg out in the slow position everytime I power up. Sometimes, it will just come up to whatever the noise/signal level is. Also it NEVER hangs when it pegs, it only takes a couple of second for it to return to normal reading. Going to begin grounding the antenna and see if that hels.

I absolutely love the 530SP. Receiver is quiet. VFO ratio is a little fast for a 75 year old Ole Codger but I'm getting there!! Sometimes drifts a 100 cycles during warm up but then stable as a rock. Using M60A and have been getting excellent reports. Thanks for your response...didn't mean to write a dissertation.

42100. AT-200 Meter Faulty?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-13 12:45:05 UTC
From: cl5ltd
Topic: 42100 Message: 42100

I have an AT-200 with an erratic and inaccurate meter.

Power output reading is considerably down on what I consider to be an accurate meter AT-200 shows a little over 50 watts - the other power meter shows closer to 100 watts. Same radio, frequency and settings (TS-520S)

When I attempt to measure SWR, when calibrating the needle swings around erratically - even when not touching the controls. Sometimes it will settle and operate as it should but it's touchy.

The SWR readings don't seem too far off my reference meter 1.5:1 showed closer to 2:1 on ATU-200

A visual inspection of the small circuit board components doesn't reveal any obvious faults or failed parts. Everything else is intact and appears complete

So I'm not confident in the readings I'm getting. What steps would group members suggest I take to further assess the unit?

Could a replacement Kenwood meter be sourced? Should I just look to salvage a similar size meter from simple SWR meter? There's plenty of low cost SWR meters around but how could I determine if the meter would suit - apart from physically fitting the ATU window

I hope there life left in this unit as tuner, SWR meter & antenna switch would be a handy addition to the station

Any advice appreciated
VK5LTD

It's quite possible that VR1, VR2 and VR3 pots are dirty. Try cleaning
them then perform the alignment again.

I think you are focusing on a minor problem. Good practice dictates you get the antenna off the SO-239 or ground it. Far more potential for ESD to damage your prize TS-530SP than worrying about S-meter deflection on power on. Rewinding L41 and replacing Q1 is no fun.

If you are using open wire feeders or ladder line to a tuner you must transition to a piece of coax. If you have no switch in that coax jumper suggest you do so or unscrew the PL-259 off back of rig.

A good antenna switch will have a ground position so you dont have to constantly screw and unscrew the PL-259. Even if you have Polyphaser or similar protection on your feedline it is smart to ground or disconnect the coax from the rig.

I always place antenna switch (Alpha-Delta)in ground position and if I am home when there is near by thunderstorms I unscrew the Pl-259 and unplug rig from 120vac line.

In old days when I ran tuned feeders we would place a non-resistor spark plug on each leg of the open wire feeder to form a spark gap and we would install a 200k to 300k ohm static drain resistor on each leg to ground. Today they would probably use a more modern GDT.

If you want to place AGC to off position it is your radio and you can do as you want, but it wont protect your receiver front end from nearby lightning and ESD.

Hello C A,
I was curious as to whether you had a problem or not and I did not explain my question. Now you know why they do that. Hope you enjoy your 530SP. Another fine piece from Kenwood. Take Terry's advice and protect it. I use the unplug method. Been doing for 40 years and it is good insurance. 73, Don K5HFG

Topic: 42105 Message: 42105

Picked up this weekend and absolutely love it. Such a pleasure to operate!

Dial calibration was out by about 25kHz so I reset this, and previous owner only used for listening which isprobably why bias current was way off but easy to set with the pot behind side panel.

Getting well over 100W on 40, 20 and 15 but no ALC signal whatsoever on 10m so presume the 12BY7 driver could be on way out?

Probably needs alignment when tool arrives (I was guy who asked about why metal hex key could crack slugs) as the Drive position is very different for peak ALC on Tx compared with peak signal receive. On the calibrator signal difference is around S7 to S2 so justifies aligning.

The receive audio is lovely- even my XYL commented on how great it sounds and she normally doesn't like sound of rigs!

I was also curious about the WWV 15MHz receive position and its use for calibrating the marker. If I tune very carefully I can sometimes hear the WWV second beeps but sometimes can't find them (maybe propagation)! Why does manual say rig must be in Tune position (with 25kHz Cal on) to adjust the marker frequency? Do you zero beat against the second beeps or a carrier tone? Is WWV actually transmitted as an AM signal?

Had some luck at a vintage radio rally I went to day after I got the 520SE. Found pair of new old stock RCA 6146Bs and a GE 12BY7A. I think the finals are ok but good to have "new" spares and the driver may be source of 10m problem. I was also on lookout for a suitable micropone - ideally MC50 - and there was one at show which had never been yout its box for same price average used ones go for on eBay. Honestly it looks brand new with shiny plugs and stand - real time capsule.

When I've finished fiddling with the rig Ihope to meet some of you on the air soon!

Hello All,
I am looking everyplace for a front panel for a 530 SP rebuild. Finished except for Face. They are very hard to find and I would consider a parts rig if it is in good outside shape. But I do not want a transformer burn out. Been there done that. To hard to clean up and still some will not come out. I hate to pester the group but, I have no where else to go.............

Thanks, Don K5HFG

Has anybody have any experience with the kenwood station monitor? As my 520s ages, it would nice to keep a better eye on things. Is there something out there newer better digital? I like the idea of getting the Kenwood accessories for a matching station, but if there is something better/cheaper/more functional..I'll consider it.

thanks

steve

Hello Dave,
No, I did not contact Bob, I figured he would see the post and call out if he has one. I have a face panel that is damaged on the bezel. It is chipped and cracked and what looks like drag gouges on the top. The rig was beat up fairly well and was a wreck inside when I got it last fall. It looks and works FB now except for the face. Gess I will just keep looking.

No Dave, What I need is a new undamaged front panel. It is dented and nicked to a great degree and I do not care to try silk screening. I want a good condition face panel. I do not like body work on these Hybrids. A good eye can always pick it out if it is not done by a professional. I do not have that luxury in my hobby budget. That is why I repair myself. Not that there is anything wrong with that, I just do not care to engage in it. My XYL already hints about how much time I spend in the shack. This could start a war I will not win. Besides, I already have a project for the next few months building some attenuation pads and doing a little experimenting. That takes precedent over the panel, plus I will have time to find what I am looking for.

I appreciate your eagerness, I am to long in the tooth for it. I want to spend what time I have left doing real radio. Hi

42115. TS-830S Bandswitch Coupler Replacement

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-14 23:09:50 UTC

Hello to the group,

The coupler on the bandswitch shaft on my TS-830S has broken/cracked inside of the PA compartment. I've got all of the covers removed and am in a bit of a quandry as how I should proceed. It almost looks like I need to disassemble the entire rf enclosure to get at the coupler. Does anyone have any experience with the proper procedure to follow to perform this type of repair? My experience is mainly on Collins S/Line and Drake gear, so any assistance would be much appreciated.

73,
Steve, N6HK

Hi Steve,

We are lucky---it's well documented with photos in at least 2 places! Also, you can order the part from either place:

http://www.k4eaa.com/couplers.htm

http://www.hybridrestore.com/coupler-mounting/

I've done this in 2 radios thus far--the TS-530S and TS-830S. Take your time, and get a LONG Allen wrench or you'll wear out your fingers...heh. Results are great!

Also, take care when trying to break the old one to get it out. On one rig, it seemed like I had trouble staying out of the way of a coil, so keep a close eye on that. Don't want to damage one.

All the HIGH VOLTAGE IS PRESENT AND COULD KILL YOU warnings apply of course!!

Steve,

As Mark has stated, but make sure you get the alignment correct. Have a look in the file section and you will see photos of the correct alginment, you will only need this if you have turn band switch and shaft turned and switch didn't. Come back if you have any problems, long Tee allen key is the best.

I agree with the use of a long T-handle allen wrench. I also use a fresh X-acto hobby knife (razor sharp blade) and I reach thru the window and cut the coupler flexible grid members. Makes for very easy removal then.

Strongly recommend you read Mike Waldrops W5RKL procedure for aligning the two band switch shafts over several times before you start. He has posted it here several times.

Be careful not to over torque the allen head (grub) screws on the replacement brass couplers. Easy to strip the threads.

Thanks to Mark, Dave and Terry for the good information regarding my problem with removing and replacing the bandswitch coupler on my '830.

I used a different procedure that I would like to share with the Group. What I did was to remove the plate tuning capacitor. This entailed unsoldering some components, but nothing too difficult. I did this as I didn't have access to a long arm metric key set. This enabled a clear shot to the coupler and shaft. I was able to use a standard set of metric keys that would've been too short otherwise to follow the more standard procedure. Anyway, I thought I would pass this on for what it's worth.

Again, thanks to this Group, for all of the great advice on the care and feeding of these classic rigs.

Steve, N6HK

Steve,

Ha! More than one way to skin a cat. Nice work.

I didn't have a long Allen wrench, either---I got by with patience and using a small pair of needle nose pliers to turn it when my fat fingers wouldn't...delicate work, but got the job done.

Nice to have a firm bandswitch now, isn't it??

73,

Mark N8MH

Sounds nice!

If you tune just below WWW frequency you will hear a side tone. When you set function to CAL25 the crystal's harmonic every 25KHz is inserted and makes side tones available, so there will be one for the WWW frequency.

If all is well, those two side tones will match, or be close enough to make a very slow beat frequency. It may help to use IF Shift to hear it.. If the WWW side tone is faint, it may help to switch the CAL25 on and off to hear and compare.

At some point in approaching a match in frequency (using the adjustment to the marker crystal to zero beat the WWW) you won't be able to hear the beat difference as audio, so you can switch to looking at the S meter - when the difference gets down to just a few Hz the meter's time base and dynamics will allow it to wiggle with the beat frequency, and as you adjust closer it will slow down and pump slowly... you can adjust to get that to slow down to as close to dead still as you feel inclined. It won't really stay there, but it will be close.

Not familiar with the SE, but the band for WWW may be either disabled or just not present in the transmit selection modes, so TUNE may be the only one that hears it for that rig.

According to the TS-520 service bulletins, no ALC indication on 10M is "normal." And that is the way it is with my 520. I assume the 520SE is the same, although there are 520 owners who say they do get ALC on 10M.

So your driver tube probably is Okay, given the amount of RF output you are getting.

Good Luck!

Robert

Sounds nice!

If you tune just below WWW frequency you will hear a side tone. When you set function to CAL25 the crystal's harmonic every 25KHz is inserted and makes side tones available, so there will be one for the WWW frequency.

If all is well, those two side tones will match, or be close enough to make a very slow beat frequency. It may help to use IF Shift to hear it.. If the WWW side tone is faint, it may help to switch the CAL25 on and off to hear and compare.

At some point in approaching a match in frequency (using the adjustment to the marker crystal to zero beat the WWW) you won't be able to hear the beat difference as audio, so you can switch to looking at the S meter - when the difference gets down to just a few Hz the meter's time base and dynamics will allow it to wiggle with the beat frequency, and as you adjust closer it will slow down and pump slowly... you can adjust to get that to slow down to as close to dead still as you feel inclined. It won't really stay there, but it will be close.

Not familiar with the SE, but the band for WWW may be either disabled or just not present in the transmit selection modes, so TUNE may be the only one that hears it for that rig.

Jerry,

When you select JJY/WWV on the band switch do you tune the VFO to zero
on the dial? Do you hear any signals with JJY/WWV selected on the band
switch?

JJY/WWV has it's own 23.895Mhz Heterodyne Oscillator crystal. If the
23.895Mhz crystal fails or it has been changed to some other crystal
frequency by some previous owner, for what ever reason, then JJY/WWV
will not work. The 520SE receives the 15Mhz WWV signal(23.895 - 8.895 = 15).

Robert:

I will probably regret wading in to this pond!

I do not doubt that you have no ALC indication on 10 meters on your TS-520. In my experience it is "common", but not "normal". I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.

I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.

I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.

I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.

Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.

Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the

CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.

There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

Sorry so long, but this is not easy subject to cover briefly.

If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.

Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.

Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Not being critical of you Robert. Just trying to help.

73s Terry K9TW

>
> According to the TS-520 service bulletins, no ALC indication on 10M is "normal." And that is the way it is with my 520. I assume the 520SE is the same, although there are 520 owners who say they do get ALC on 10M.

42126. Driver Tube Testing, Driver Tube Power, DRV 50 ohm Dummy Load

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-16 14:10:44 UTC
From: Terry Wagoner
Topic: 42126 Message: 42126

1. How can I test the Driver Tube?
2. What is the Driver Tube power?
3. Can I lift the Blue DRV lead and terminate with a 50 ohm dummy load to test the Driver tube?

1. I have posted numerous times on how to test the Driver tube stage. Standard test is performed in CW mode, SG off, Heaters on. Key rig and peak RF Drive control for full scale ALC deflection (not top of ALC black box). If meter pegs just lower the Car Level pot to set indication right on FSD. Do this on each band. Let it rest a few seconds between each band. Good Driver tube stage will produce full scale deflection and not drift off FSD. Just leave keyed for a few seconds. Tube is running Class A and this test will give it a good work out and shield will get quite hot.

2. You can calculate or measure Dc input power just like you would for the 6146 finals. DC input power = Plate volts x Plate current. From schematic or voltage chart then P = 290vdc x 30ma = 8.7 watts or approx 9 watts dc input power. Where did 30 ma come from? Measure or use Cathode voltage and cathode resistance values from schematics. Measuring is better. Assume cathode resistance = 150 ohms and cathode voltage = 5 volts. I = E/R I = 5/150 = 33 ma. In my experience the Driver tube cathode current ranges from approx 27ma to 35ma. Tube data sheets show max plate current is 27 ma so the Kenwood hybrids are pushing the Driver tube to max plate current. Note: Cathode current includes SG current so Plate current is really slightly less.

3. Calculating or measuring the output power is a little more involved. Class A amplifiers that are capacitively coupled have a maximum efficiency of 25%. In practice far less than this. Assuming 9 watts dc input then max output power would be approx 2.25 watts. It is generally accepted that the maximum rf output power of the 12BY7A is approx 2 watts.

A Class AB1 amplifier (our 6146 finals) requires Zero drive power. The Driver tube only needs to provide RF voltage swing. There is no grid current. With Zero current then power equals zero as P = E x I and if I = zero then P = zero. This isnt technically accurate as the Driver tube does have to provide the charge/discharge current at an RF rate for the 6146 inter-electrode capacitance. So a small amount of power is provided. I have seen estimates of 1% to 2% of RF output power. So at 100 watts out that would be approx 1 to 2 watts of Drive power is consumed charging this capacitance.

The Driver tube is working into the control grid of the 6146 finals. What Resistance does this present? Well we are looking at Admittance and not dc ohmic resistance, which is a little hard to understand. Requires digging in to Conductance and Susceptance. Can think of it as a hypothetical resistor and capacitor in shunt from the 6146 grid to ground. Basically the Driver tube is seeing the Conductance of the control grids. Actual calculations of the grid resistance are complex. Rough calc is Rg = Egrid squared/2xPd. Pd = peak power. So assuming grid bias is -62 and power is 2 watts then 62 squared/2x2 = 3844/4 = 961 ohms. So the Driver tube is looking at approx 1k ohm and not 50 ohms.

This is why you do not want to lift the Blue DRV lead and terminate it with a 50 ohm dummy load resistor.

My own testing on a TS830 is as follows.
1.Lift Blue DRV lead off Final board.
2. Connect 1k ohm 2 watt metal film resistor from blue lead to chassis ground. Note: My resistor measured 980 ohms.
3. Place SG off
4. Connect Rf millivolt meter or O-scope across dummy load resistor
5. Flip to send and peak the Drive control for maximum RF voltage across the 1k dummy load. Note: there will be no ALC meter indication as finals are out of picture.

Plate voltage = 290 vdc
Cathode current = 32ma
DC input power = 9.3 watts
RF voltage across 1k dummy load = 31 rms volts
RF power = E squared/R = 31x31/980 ohms = .98 watts or 1 watt output

So efficiency is very poor at approx 1/9.3 = .107 = 10.7 %

I tried a variety of values for the lifted DRV lead dummy load ranging from 50 ohms to 47k ohms and I found values in the 1k to 2k ohm range produced the maximum RF voltage drop for approx 1 watt output power.

Summary:
1. No need to lift DRV lead and terminate with dummy load to test 12BY7A Driver stage. Use standard CW full scale ALC deflection test.
2. Driver tube DC input power is approx 9 watts and plate current at 32ma is at max of tube data sheet recommended value.
3. In theory Class AB1 6146 final control grids require no RF drive power only need rf voltage swing. No grid current means no power.
4. In practice Driver tube does have to provide power to charge and discharge the 6146 control grid inter-electrode capacitance. I suppose could calculate the Xc for this capacitance and calculate this current. I have not done this. I think you would need to calculate the Cgk in series with the Cgp to arrive at the total capacitance. It would be a small Pf value.
5. The approx Z that the 6146 control grids present to the Driver tube is 1000 ohms and not 50 ohms. With DRV terminated with 1k ohm dummy load max RF output is approx 1 watt.
6. No reason beyond academic to know the Driver tube input and output power. Standard testing is to use TX Level Diagrams and measure the RF voltage at Driver tube Plate and at 6146 control grids. If spec values you know Driver stage is producing design RF output power.

Thanks for the off list questions. If anyone has other experience or sees flaws in my logic or testing please share with us.

73s Terry K9TW

Many thanks for valuable info Terry.

Different views from similarly experienced owners, so what I'll do is test whether a new driver valve - after checking voltages described here - makes any difference to 10m ALC.

Plenty of time anyway till 10m shows signs of life!

Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
>
> There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.
>
> Sorry so long, but this is not easy subject to cover briefly.
>
> If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
>
> Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
>
> Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Thanks a lot Paul.

So from what you say it sounds as if the rig is actually creating a 15MHz transmit signal on WWV/tune position. I think I had wrong idea that in this mode the crystal calibrator generated frequency was being heterodyned with the broadcast WWV signal, but I suppose you only hear that in Receive mode.

Please re-read your receiver theory,
The radio has in internal signal at the IF frequency going into the product detector it is not transmitting on the WWV freq ! Without this you would not hear SSB or CW signals in your loudspeaker (or phones). Since WWV is an AM transmission you hear the carrier as a tone along with the modulation, unless you tune the dial for Zero-beat.
To set your calibrator you can set your mode to SSB or CW as long as you can hear the calibtrator signal beating with WWV.

OK thanks very much for making it clear.

I was confused by fact that in the 520SE the manual instructions are to adjust the calibration generator frequency in "tune" mode (which I associate with transmitting, albeit with no power to finals), even though the 520SE has a normal recive position for WWV too

I do hear the sidetone when tuning off the WWV frequency, but wasn't sure why 25kHz marker adjust had to be done in Tune mode.

Thanks again! I will re-read circuit description in manual.

It hasnt been made clear at all.

There is a reason why they want you to "calibrate" your dial in the Tune position of the mode switch. There are three carrier oscillators and placing the rig in Tune selects the correct oscillator crystal so that you can hear the 700hz CW offset zero beat and align your dial to the center mark.

The crystal calibrator is required of course because you have no digital dial and must use the bandswitch, vfo dial and sub dials to determine where you are at. You cannot simply rely on the VFO dial as with all air variable capacitor VFOs there are linearity problems. Not easy to get VFO to accurately track across full travel. Crystal Calibrator or "Marker" gives you birdies or markers every 25khz across the range of the VFO. The accuracy of these markers is no better than the accuracy of the Markers base crystal oscillator frequency. This oscillator can and should be adjusted.

So your first step is checking the accuracy of your Marker against some frequency standard. Absent a calibrated Frequency Counter which is the easiest method your Kenwood provides the ability to receive off air WWV signals. With either frequency source you use the zero beat method to adjust the trimmer capacitor on your Marker board to ensure your crystal oscillator is accurate. This way the divided down outputs at 25 khz will be reasonably accurate. Use a non metal tuning tool to make this trimmer cap adjustment. TC-1 trimmer is located on the Marker board on the top left rear of the rig.

If you have no experience with zero beating it can be a little difficult. Place your AGC in Fast position and as someone mentioned as you approach Zero beat you will hear a woosh-woosh sound in speaker and will see a flutter on the S-meter. The closer you get to zero beat the slower the woosh and slower the S-meter flutter will be.

Some of the problems include propagation and doppler shift and the roll off on low end of our SSB filters and of course the human ear. With a good strong WWV signal, AGC on Fast, a light touch on VFO knob and a little practice you can get it close.

After you adjust your Marker trimmer cap you can then tune the VFO to say 7.050 on your analog dial and turn on the Marker and in TUNE mode you can slip the dial alignment to the center mark which will then give you accurate 700 hz offset.

VFO tracking will depend on how well your VFO L/C has been adjusted. The TS-520S service manual describes this alignment step.

You cannot expect the dial alignment you make at 7.050 to track as you move up in frequency. You will have to use the Marker as you move from one end of the VFO travel to other.

Because you have VFO accuracy limitations it is best to stay well clear of the band limits of the terms of your license. Today with so many modern digital dial rigs on the air you can also check accuracy by listening to some of the long running nets.

Sorry I mis-spoke. If you use a frequency counter to adjust your Marker oscillator frequency you do not use the "zero beat" method.

You simply connect the counter to the Marker output and adjust the trimmer capacitor. Dont connect the counter to the collector of the oscillator transistor as it will pull the oscillator crystal frequency.

I have the same problem on my 520se. You might try the alignment procedure. I was able to hear WWV after doing this but like you it's well below noise and doesn't move the S meter. My other radios hear it S9.

I'm hoping to dive into it more later tonight.

If you have not downloaded the TS-520S service manual and studied it suggest that it is a must. It will tell you how to align the front end for WWV reception. You need a RF signal generator and usually do it in two passes. Inject 15mhz signal into the SO-239 antenna connector at approx 500uv or -53dBm and adjust T4, T5,and T3 on the RF board. Reduce sig gen attenutor for approx 50uv or -73dBm level and repeak T4, T5 and T3.

If you do not have a sig gen with a calibrated output attenuator then inject a test signal on 20 meters around 14.2 mhz and adjust your sig gen for S9 indication. Then set sig gen frequency to 15 mhz and do not touch the output level and use that level to align the WWV coils.

Absent any kind of RF sig gen then use the Marker signal. Section 6 of your Operating manual describes how to use the Marker for WWV alignment.

Thanks for the tip. I gave the VRs and rotary switches a blast of contact cleaner followed by a blast of compressed air.

The needle is no longer moving erratically so the clean up worked.

However, power output readings are still well down on my reference meter when both connected in line. On 20 m shows 70 watts when other meter shows 100 watts -

I haven't made any internal adjustments. All components appear OK- no obvious burntout parts.

I haven't been to find any info on correcting this inaccurate readings.

SWR readings seem to be more accurate.

What to try next?

Chris,

Go to 10m and tune the radio, once you have peak wattage, turn power down and leave tranmitting and see if the ALC\wattage drops, if it does means 12by7a or 6146\s2001a tubes are prob on the way out may need to be replaced, this is very common.

Great. This makes things a lot simpler for you.

If you have a good freq counter you wont need WWV. Only reason Kenwood provided the ability to receive WWV is so you had a precise signal source to adjust your internal Crystal Calibrator (Marker). Ability to receive WWV off air signals makes the rig self sufficient for owner who doesnt have a freq counter. Back in 70s the average ham did not own a cheap, accurate, digital frequency counter. If you were lucky you might have had a military surplus BC221. Analog dials with 5kc readout were the norm for a lot of us. I remember my first Heath LMO with 1kc readout and I thought I was in heaven! Back then we took it very seriously if we got a "pinks slip" from FCC for out of band operation.

Once you adjust your crystal oscillator so it is running very close to 2.5mhz (the 520SE did not use more common 100khz crystal)then you will be able to trust that the 25khz birdies or markers that it produces are accurate and you will use them to adjust your dial.

Remember you need to use the Tune position to align dial for CW operation.

Have Fun

Well understand being on fixed income. You can get by with a LC type RF signal generator as your first sig gen. Most all of us started there and soon learned the limitations and graduated to better units.

Biggest limitation is no calibrated step attenuator. Also best to use a freq counter with them as dials are not precise. They also may drift, have leakage, and can be microphonic. Leakage can be a real problem if you are trying to do low signal level RF and IF alignment. Sometimes they make better transmitters than sig gens!

If you are going to start with a LC type unit suggest Heath as readily available and can buy a spare parts unit to keep the good one running. The SG series are really vintage and I would probably move up to something like a Heath IG-102. I had a EICO 324 for some years. BK also made LC units. The best BK is the E-200D.

Above the Heath, Knight, Eico level many hams stepped up to URM/25D military and the HP-606 was very popular. These are large heavy units and also getting long in the tooth.

Today can find several new Chinese made units selling on Ebay.

Lasty might want to look at DDS technology. There are some kits available for digital VFOs which can also serve as sig gens.

If you buy a IG-102 Heath you can use it for signal injection and signal tracing. Where it falls down is being able to set a precise output level such as 50uv to calibrate your S-meter.

One way around that is if you have a good commercial receiver with accurate and known S meter units you can drive it with the IG-102 and set the output level switches and pot for say an S9 indication and then use an external step attenuator to obtain reasonably accurate lower rf output levels for alignment work. Step attenuators can be built of purchased in kit or assembled units. Elecraft and Hendricks QRP make kits.

If you get serious about bench work then a HP8640B or Wavetek 3002 PLL units are popular way to go, but now in the several hundred dollars range for a functional one. It all depends on your priorities and how you chose to spend your discretionary income.

There are 3 or 4 IG-102 units on Ebay right now in the $10 to $20 dollar range.

Good Luck

If I may add to Terry's comments.

The IG-102 is a fair signal generator. I have one and I use it for basic IF and detector testing. I replaced the screw on connectors (there are 2, one for audio and one for RF) with Female BNCs. A BNC "T" connector is required in order to connect the frequency counter AND the connecting cable to the signal generators (I use an inexpensive scope probe).

The IG-102 and the URM-25D generators will drift and, as Terry said, a frequency counter is a must when using these generators. I use a Sinometer VC-2000 counter, available on eBay to ensure the IG-102 and URM-25D generators are on frequency. I always power up the signal generators and allow them to warm up for at least 30 minutes or more before using them.

The IG-102 has a LF limitation, 100Khz. It will work for receiver's having a 455Khz IF. The URM-25D LF low end is 10Khz so it will work with receiver's having an IF as low as 50Khz (NC-300/303, Apache RX-1, and others).

As for DDS generators, there are quite a few that can be used as signal generators (see eBay using DDS as the search phrase). The N3ZI DDS VFO, for example, can be used as a signal generator (RF only) up to approximately 30Mhz. Most, not all, DDS generators are powered from 12VDC. The N3ZI DDS VFO for example, requires 12VDC at less than an amp using a power cube/brick (Walwart). Most power cubes/brick's output voltage is NOT regulated! For example, a cube/brick that's rated at 12VDC a 1 amp, can have an "unloaded" output voltage at high as "19VDC"!! I found some 12VDC 6 amp "regulated" power bricks on eBay, they are designed to power digital cameras. Their output "unloaded" DC voltage is 12.3VDC at 6 amps. Also, not all cube/brick's output connector's center pin is positive, some have a "negative" potential on the center pin. So PAY ATTENTION, DO NOT assume anything!!

Thanks Mike for adding your very good experience with rf sig gens and wall worts open circuit high voltage. I did not mention the Heath IG-5280 which I think replaced the IG-102? It is solid state unit, but I have no experience with it. I never really liked the look of the later Heath Kit packaging (late 80s to early 90s). Probably not fair as performance may have been OK, but the packages looked cheap. I dont think the 5280 had calibrated RF output attenuator.

I am really surprised that you dont see reasonably priced DDS RF sig gen kit. Seems like would not be too hard to add a low pass filter, maybe a wide band post amp to get the level up, and a step attenuator to one of the VFO kits.

Anyone who owns and intends to maintain their own hybrid needs a decent rf sig generator. A reasonably priced DDS unit would fill that bill nicely. All the old popular units come with their share of problems from unavailable parts, cracked drive gears, PLL unlock etc.

Dave- I will do that with the radio and report back - there is a set of spare tubes with the radio but I don't know condition.

However it's the ATU power reading correction I was asking about in this case. The power level reading is well down on correct level. Need to fix this

The IG-5280 is a simple RF signal generator, basically the same as the IG-102 except it's solid state. The nice thing about the IG-5280 is it's powered by batteries for field use. One can use a Walwart for shack use (see the manual for details). The IG-5280 is one of a group of test gear. I bought the Heathkit IB-5281 RLC Bridge which is part of the IG-5280 test gear set. It operates from two 9 volt batteries. I wouldn't use it for any precision work. I thought about purchasing the IG-5280 signal generator at one time but decided not to. I don't know what the stability of the IG-5280 is but I would assume a frequency counter connected to its output would be necessary!

Another nice piece of test gear is the all solid state IM-17 VTVM. It runs on 2 batteries, a single 1.5 volt "C" cell for ohms and a 8.4 volt battery for the VTVM circuit (same type and size as a 9 volt battery). I had a couple of 9 volt batteries laying around, checked their voltages and found one was at 8.4VDC so I used it. That was a year ago and the VTVM is still working fine. I use it quite often. It's a nice small VTVM for field work where AC power is not available. A 9 volt battery can be used in place of the 8.4 volt battery, see the link below for details on modifying the IM-17 to use a 9 volt battery:

http://www.heathkit.nu/heathkit_nu_IM-17.html

I found a "DURACELL PROCELL DA-1466" 8.4 volt Zinc Air Medical Battery on eBay. The price varies from $4 to $19.99 depending on the seller. There are quite a few NEW PROCELL batteries in sealed packaging on eBay right now. One seller is selling 6 new batteries in their sealed packaging for $7.50 plus shipping. The PROCELL battery doesn't start losing it's charge until taken out of its sealed packaging and installed in the circuit. The battery can sit on the shelf for ages, providing the sealed packaging is not tampered with or broken, and still work when removed from it's sealed packaging.

Mike:

I just looked at the IM-17 and the specs say it is 11meg ohm input Z on all dc ranges. That is equiv to the VTVMs. It also appears to have a nice 200ua large meter movement. I wonder about the hinge life on the case? Having to lay it down to view the meter isnt as good for bench work. Not too thrilled with the fixed test leads, but not a big deal. Also the meter ranges of the VTVMs offer a little better overlap, but those of the IM-17 will work just fine.

I will start telling Kenwood owners who have no VTVM to consider the IM-17 in lieu of IM-18 type VTVMs if they have budget concerns or cant find a decent VTVM. I see on Ebay that they go cheaper than a VTVM. It is not unusual to have to spend a little more money on your first VTVM when you get it to replace electrolytic filter cap in power supply and to replace the two tubes.

Only concern I have is with all battery powered gear it is a must to replace batteries annually. I place a piece of blue painters masking tape on bottom of any battery powered test gear with battery date on it and I religiously replace the batteries once a year even if they still have good voltage. I do this same time I do the house smoke detectors.

I once destroyed the battery connections inside a very expensive meter when a Duracell alkaline leaked and corroded them. The acid also puked on to the PC board and not easy to clean it off. From then on I decided to spring for a $3.00 battery versus wrecking a piece of test gear.

I wonder if they sold the IM-17 primarily for the auto repair techs? If so, would want to get good close up pictures to make sure unit was not grease stained.

Thanks for sharing. Looks like a good option if you dont have a VTVM or analog FET meter on your bench.

Terry

Mike: I forgot to mention it would probably be pretty easy to place a silicon rectifier diode in series with a 9vdc duracell to drop the voltage close to 8.4vdc?

I think they went with the mercury to have essentially flat 8.4vdc output thru its life and thus hold the meter calibration better. It might even cal OK with the 9vdc and if changed once a year not have to worry about losing accuracy?

42151. Original 520-was drifting on transmit, then let smoke out

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Hi folks! NE5N here. My 520 purchased new in 1976 came out of storage in Nov. and after cleaning up wafer switches, contacts, etc. seemed to be working OK. Then ragchew friends started telling me that it was drifting on transmit (I never noticed any drift on receive after normal warm-up), but after unkeying, it would be off freq. So I got the idea to plug in the external VFO to see if that would help. Unfortunately grabbed TS700SP VFO (very similar in appearance-especially to tired old guy) and plugged in. On power up, there was an instant dead short somewhere which blew the fuse and let out a large amount of smoke, with associated burned insulation and component smells. Any pointers on where the drift problem might be coming from once I sort out the short?
Thanks!

Well your idea to reach for external VFO was a good one. If rig still drifts on the external VFO then almost always have a problem with AVR board regulated 9VDC supply. If no drift while on external VFO then problem likely inside the internal VFO. Try loosening and tightening the PC board mounting screws, re-heating solder connections, cleaning the PC board. Not an easy task.

If frequency is jumping or dead spots or noisy (very different than drift) then would indicate that the VFO air variable capacitor rotor shaft wiper contact needs cleaning. People often confuse the two symptoms. Two very different problems and causes.

If 9vdc is source of drift you would think it would manifest itself on transmit and on receive. You can power the internal VFO with a dc bench supply or a 9vdc battery. You might want to parallel two fresh 9vdc batteries. Unplug your Pin 8/9 jumper and connect 9vdc battery to Pin 8 and chassis ground. VFO should pull approx 50 to 60ma.

If you now have no drift you need to look at AVR board.

Sorry got my rigs mixed up.

Your TS-520 vfo will pull approx 25 ma. So a single fresh 9vdc battery at Pin 8 will power it long enough for you to make QSO to see if you are still getting reports of frequency drift.

The TS-830 VFO pulls approx 50 ma. Old age and too many rigs in the dusty old file cabinet between the ears!

Terry K9TW

I forgot to ask do you have a frequency counter that you could watch your output frequency as you transmit into a dummy load and to monitor your VFO frequency with?

Also make sure the people reporting the frequency drift are reporting it correctly. Ask them if they have to slowly tune their VFO or RIT to follow you up or down in frequency. Or is your frequency jumping up or down.

Well I popped in "new" 12BY7A driver.

Rewarded with much healthier ALC on 15m (before had been unstable on that band) but still no ALC whatsoever on 10m. I also used switch cleaner on band switch and worked it in, in case of contact problem on 10m.

Next I will check the grid volatfes and cathode resistors as Terry suggested.

I also wondered if coil alignment may be part of answer so alsomtook off bottom of case.

The bad news is that the nylon hex toool I got on ebay was too big for the cores (have ordered one from Ken K4EAA).

The good news is that I examined all the slugs very carefully under bright light. Only one appears crackdd - the 3.5MHz oscillator coil. So when proper tool arrives I can align rig properly.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> >

> > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> >
> > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> >
> > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> >
> > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> >
> > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> >
> > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.
> >

> >

> > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> >
> > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> >
> > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Topic: 42105 Message: 42156

Here are my readings from my personal TS-520 serial number 040234:

1. Full load on 28.500 Mhz = 85 watts output @200 ma into 50 ohm dummy load.
2. ALC indication is full scale deflection(FSD)ie the needle is far right at "350 ma" with Car Level Pot at position "8" and Drive Control peaked at 1230.
3. DC bias voltage at 6146 control grid Pin 5 = -85.6vdc cutoff bias in RX mode and -51.4 vdc operating bias in TX mode.
4. RF drive voltage at 6146 control grid Pin 5 = 43.0 rms volts measured with a Boonton 92E RF millivolt meter.

43 x 1.414 = 60.8 peak rf volts
60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.

-51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.

So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

You will need a 3 diode RF probe and VTVM, or an O-scope, or an RF Millivolt meter to make the RF drive measurements.

Report back the RF output level, the operating bias voltage, and RF drive voltage and based on those I can point you to next place to look.

Terry
K9TW

He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design

engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > >
> > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > >
> > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > >
> > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.

> > >
> > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid

current. No Ua grid current means no ALC indication. This is the first place to start.

42157. My TS-820 got sick... :-(

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-20 03:50:50 UTC
From: coyoteinventor@ymail.com
Topic: 42157 Message: 42157

Hi group! I'm new in this forum and in ham radio, and I'm in need of some help from the experts. ;-)

I bought a Kenwood TS-820 a month ago or so, and it's been working pretty well other than the common issues (drifting VFO, LCD going on/off, and weakening final tubes) I have not had time to look into some of the solutions mentioned in this forum.

Last night, while using the radio, I stopped receiving for a few seconds (everything went quiet) and then back to normal. Today I used the radio for a while with no problems, then turned it off, and, when I came back to it a couple of hours later, no receive at all, even after fiddling with it for 15 minutes. :-(

So, the symptoms: on SSB, I crank up the RF gain all the way up, and the AF gain quite high, and I barely hear things (even the noise I can hardly hear when usually, with these settings, I would be going deaf!). If I crank up the AF gain all the way up, I get some type of feedback (loud beep). If I switch to CW or TUN, I also get a loud feedback (louder). If I transmit to a dummy load, I am getting less than 50% of my normal transmit power.

Any ideas what could have gone bad?

Thanks in advance for your help!

--Cesar-- K1TNT

42158. Re: Progress report new 520SE acquisition

Thanks for such detailed readings Terry.

I won't be home to check my rig till the weekend but will report then. Before leaving today I did have time just to put a freq counter on the marker output. You are absolutely correct that SE has a 2.5MHz crystal, but at the output my counter was picking up 50kHz signal (forget how many decimal places but several!). Must be some peculiarity of the counter that determines which 25kHz harmonicis picked up (the service manual says to trim for an even multiple harmoic). So at least the calibrator is set correctly without benefit of strong WWV signal, but I guess I knew that as I could compare it with my FT817ND frequency display on same signal, and the sub-dial was also within 1kHz on some of the regular nets Iisten to.

Thanks again for terrific help.

42159. Coil board conundrum

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-20 10:23:02 UTC
From: adrian.langford@ymail.com
Topic: 42159 Message: 42159

On Ken K4EAA's site he discusses rewinding coils if a ferrite slug gets stuck/broken and new formeri s needed.

Was pleased to find only one of my 520SE coils is cracked (3.5 mhz osc), but when I was looking at the board I saw the band switch shaft goes right through it!

So how would anyone be able to desolder any of the coils, without major surgery? Are you meant to desolder former while board is still in place? That looks extremely tricky given narrow space between each of the coil boards.

Has anyone here ever removed and replaced one of these coils, and if so how?

Adrian-it is OK that your counter saw 50khz, but need to make sure the "decimal places" were all 00000 or 99999 or shifting back and forth from 99999 to 00000. If not need to adjust trimmer cap.

I would use your counter next and see how the VFO tracks from Zero to 600 (full travel of the VFO air variable).

Connect the counter to the External VFO socket Pin 1 or if you have top cover off connect at the Out terminal post on the AVR board.

1. Zero = 5.500 mhz - if off adjust with TC-1 inside the VFO
2. 600 = 4.900 mhz - if off adjust with L1 inside the VFO

Fig 20 in service manual shows location of these two adjustments.

You will have to go back and forth several times to get the best tracking.

If you have a rf probe/vtvm or a O-scope can also measure the VFO output level. Should be no less than 0.9v rms or 2.54 P-P.

Terry K9TW

One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > >
> > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > >
> > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.

> > > > >
> > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > >
> > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > >
> > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > >
> > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > >
> > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > >
> > > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Oh, and one more thing I forgot to mention, which might be important.

Even though I can not hear hardly anything, the needle in the meter of the TS-820 moves all the way to the right (on all meter selections), but when I transmit it goes back to the left and moves a little bit as I talk.

Thanks again!

Cesar,

When the 820 is in "receive", NONE of the meter switch positions work, they are ALL disabled. The only time the meter switch positions are active is in "transmit".

Okay, first do your mean that the coil slug is cracked?

Second, what you you mean that the "band switch shaft goes right through it?"

If it is a slug, in some cases I have used a drop of superglue and a jeweler's screwdriver to extract the broken slug. Then you can replace it with a similar one taken from another coil. Best source of such slugs are old CB radios, but places such as All Electronics do sell new IF coils that might have slugs that would work.

You need to get some small wooden dowels and make yourself some tuning tools that will fit the slugs and will not crack them.

Good Luck!

Robert

If S-meter is pegged full scale right then your AGC bus is not seeing RF-1 and you will have no receive as the RF and IF amp mosfets have very low or no control voltage on Gate 2.

Measure RF-1 and clean Aux relay contacts for starters.

Yes all the bandswitch boards hang off the RF board and the bandswitch shaft runs thru them. It is not uncommon to find cracked tuned slugs and also the fiber coil formers twisted off the mounting pins that solder to the board. This happens when someone torques on the core trying to free it and twists the coil former. I hate to see this. Ham fisted work.

Cracked cores can be replaced as others suggest, but I am afraid best way to replace coil formers and/or het osc crytals is to pull the boards. Not an easy task. If you try to do it in place you risk lifting a foil. You may want to contact Bob Mansker and see what he gets for a complete set of boards. He may have a set with no cracked cores and no formers twisted off the mounts.

If you get a good set of boards from Bob suggest you use a tooth pick or artist brush and apply small drop of Tri-flow lube at top edge of cores and work back and forth to free them before installing in the rig. Some folks use WD-40. Whatever you use just apply very sparingly.

Not an easy job but can be done. I have done several and just need to take your time. Just pay close attention to the shaft coupler orientation between the bandswitch boards shaft and the PA cage bandswitch shaft(under the metal shield can cover).

Apart from that single cracked 3.5 slug all the cores are ok and all formers correctly attached.

As I understand it the OSC coils not involved in aligning Rx and Tx, so when I get correct tool I will peak the ANT, MIX and DRIVE coils.

I will be sure to take your advice on careful lubeing of the slugs before I attempt to move any slugs. Don't want to break anything trying to fix it!

Sorry for ambiguity - the slug is cracked but luckily not on coil critical for alignment as I have oscillation for 80m.

The RF boards on which the could sit have a hole through each board, and they are skewered by the band switch shaft as it heads for finals cage. I was just curious about how people tackled pulling such a board - it looks almost impossible!

Thanks for your tips on sources for slugs/coils and correct tool.

I do not agree with that. I would not assume that former owners have peaked the Het Osc coils properly. I would adjust them prior to doing Ant, Mixer, and Drive coils for couple of reasons.

1. If not set properly the oscillators may not reliably start each time selected by the bandswitch. Should not be set on the fast side of the response curve. Service manual describes how to adjust.

2. The Het Osc signal is the Local Oscillator (LO) signal for the Transmit and Receive Mixers. It is important to have correct LO injection level for proper mixer action.

OK Terry thanks for correction - I thought that as I could receive ok on all bands then I could leave LO coils as they were. But now I will adjust as per manual, apart from the cracked 3.5MHz core.

Come to think of it I've never heard anything on 10m, but thought that's just conditions. Could I have no ALC because the 28 LO is not oscillating?

coil formers and/or het osc crytals is to pull the boards. Not an easy task. If you try to do it in place you risk lifting a foil. You may want to contact Bob Mansker and see what he gets for a complete set of boards. He may have a set with no cracked cores and no formers twisted off the mounts.
> > >
> > > If you get a good set of boards from Bob suggest you use a tooth pick or artist brush and apply small drop of Tri-flow lube at top edge of cores and work back and forth to free them before installing in the rig. Some folks use WD-40. Whatever you use just apply very sparingly.

Yes if Het Osc isnt oscillating on any band will have no RX on that band and no TX. I thought you had RF output on 10 and just no ALC indication. If you have RF output you have to have Het Osc running as I mentioned it is the LO signal for Q3 TX Mixer.

I am not sure who counseled that you could skip it, but if rig was on my bench and you were paying me for an alignment it would get performed. If you have no RX and TX on 10 mtrs even more reason to do it now.

Top 10 reasons (ok 3!)

1. Make sure adjusted properly by former owner and no bad xtals (they do age and fail).
2. Make sure your oscillators are running on 10 meters bandswitch positions.
3. So you can learn how to do it. Fun!

As a point of interest design engineers establish Mixer LO injection levels so it is not too high or too low. If too high can cause problems with carrier in the Mixer output and/or spurs and worse case high 2nd harmonic content (2 x 8.830 = 17.660 mhz). Only way to know for sure is look at output with Spectrum Analyzer or to listen on a General Coverage receiver. If LO level is set too low can have increased Mixer conversion loss which would probably be more concern for the Receiver mixer.

In practice with your TS520 about worse case would be as found adjustment set so the oscillator doesnt start reliably each time it is selected.

You can adjust using the "listening method" described in Sect 6 of your operating manual or more precisely using method described in the Service Manual. If you measure you should have approx 1.5rms rf volts at TP-3 on RF board.

My technique to remove a cracked slug is to drill it out. Before you think I'm crazy, let me explain. I have a set of numbered drill bits. I start with the small bits and see if it fits through the hex hole in the slug and keep going until I find the first drill that doesn't slide through. I then drill through the slug hole with that size by hand. I slowly twist the drill by hand. I do this over a newspaper because the ferrite will come out as dust. I also put on a dust mask. I then go to the next larger size or maybe up one size. The nice thing about numbered drill bits is that they go up in size by pretty small increments. I repeat this process again and again. The powdered iron is very brittle and eventually the walls of the slug become thin enough that the slug breaks into pieces that fall out. I have done this about 5 or 6 times on various gear and never damaged a coil form.

Okay, first do your mean that the coil slug is cracked?

Second, what you you mean that the "band switch shaft goes right through it?"

If it is a slug, in some cases I have used a drop of superglue and a jeweler's screwdriver to extract the broken slug. Then you can replace it with a similar one taken from another coil. Best source of such slugs are old CB radios, but places such as All Electronics do sell new IF coils that might have slugs that would work.

You need to get some small wooden dowels and make yourself some tuning tools that will fit the slugs and will not crack them.

Good Luck!

Robert

Based on that (very helpful!) description I probably do have oscillation on 28MHz. I do have RF output on that band but it's very low - all other bands 100W sometimes more, but on 28MHz maybe 20W max.

I can adjust the oscillator coils on a scope.

That's a great tip thanks.

Not crazy at all - I work on old cars for fun and drilling out seized bolts using similarprocedurev(but not by hand!) is routine.

But would not have occurred to me to usevthisvtechnique on the slugs.

This is a fantastic group! Full of know-how and people generous in sharing it.

Cesar, are you sure you have the RF gain all the way up, full CW? Your RX symptoms match having the RF gain all the way down, CCW.

I have a small drill chuck that has a 1/4 inch hex shaft that was intended to be used with a stick type power screwdriver. Its great for holding drill bits up to about 1/4 inch diameter. I often use it to give me a better grip on the bit but I still turn it by hand.

Terry (K9TW),
Thanks for your suggestions. After looking at the schematics for a while I think I found what gate you are referring to; is it the gate2 on the Q1 in the RF Unit board? Or is it Q8? I'll have to figure out where it physically is located once I open up the rig. ;-)
I was not clear about the relays you were referring to. Can you tell me in which board they are and maybe their component name/number so I can try to find them in the schematic?

Jay (kb9wwq): yes, the RF gain is all the way up. ;-)

pretty well other than the common issues (drifting VFO, LCD going on/off, and weakening final tubes) I have not had time to look into some of the solutions mentioned in this forum.
> > >
> > > Last night, while using the radio, I stopped receiving for a few seconds (everything went quiet) and then back to normal. Today I used the radio for a while with no problems, then turned it off, and, when I came back to it a couple of hours later, no receive at all, even after fiddling with it for 15 minutes. :-(
> > >

You do not need to locate the devices or measure Gate 2 voltage at them.

There are several places you can measure the AGC bus voltage. On the IF board at Conn IF-3 Pin 11 for example. You need at least a 10 to 11 meg ohm meter. Even that meter will pull the voltage down some. Should have approx 3 vdc with RF gain full CW. If lower or missing common to start by measuring at it source and cleaning Aux relay contacts that switch it.

A short lesson....The RF and IF amplifiers in the radio are all dual gate mosfets. We call these "gain controlled" stages. We use a variable positive dc voltage (approx 3.5vdc) applied to Gate 2 of these devices to automatically control the gain of these devices. We call this control voltage AGC. This 3.5 vdc control voltage is derived from the RF-1 voltage on the AF-AVR board. With approx 3.5vdc applied to the Gate 2 of these devices they have maximum gain and as the voltage is lowered the gain is lowered (assuming all other required dc voltages to the devices is to spec).

Two things normally lower this control voltage....receiving a strong off air signal and you running RF gain pot back CCW. The S-meter simply monitors the AGC bus line and when it sees the voltage go down it moves the meter up scale. Also, If the AF-AVR board fails you will have no RF-1 to supply the AGC bus so that is why I suggested you also measure it.

You have two identical relays in the radio. One is the Aux relay that controls functions like switching the AGC and ALC bus line voltage and the other is your Antenna TR relay. These are plug in relays and very easy to remove and clean. Pull the Aux relay and carefully remove the plastic cover and clean the NC and NO contacts by wetting strip of printer paper with Deoxit and placing between the contacts and applying gentle pressure to the movable armature and pull the paper thru. Should see black traces on the paper. Do this several times and then blow out relay with canned air.

When you report you had good receive one moment and then the level went down or became nearly non-existent and the S-meter is now pegged it sounds like the AGC bus voltage available at the IF Board and RF board to be applied to Gate 2 of the IF and Rf amp devices is very low.

So I still recommend you check RF-1 on the AVR board and make sure it is available and set per the service manual. First step in alignment is checking and setting the regulated 9vdc and the RF-1 voltages.

Remove the bottom cover of the radio after line cord has been unplugged and rig allowed to sit for awhile to ensure filter caps have bled off. The Aux Relay is about in center of radio next to two vertically oriented filter capacitors about on a line back from the VFO knob. The Ant relay is under a metal shield can in rear corner. You can remove both and clean contacts. Some folks rotate the position of these relays from time to time to place them in different service. Kens Electronics in Kalamazoo Mich has NOS replacements. He has a website. Not a bad idea to have a spare.

42178. ts-820. Added CW filter. CAR control must be >8 to achieve full power tuning?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Hello Hybrid group. I have an operational question for our team.

On my tech special TS-820 which was working pretty well, I added a used TRIO CW filter. At some point after that, (maybe right away, I can't recall.) I now require a lot of CAR control while tuning up to get to full power. Example: I have to crank the CAR control above "8" on 20 meters to get full IP current while tuning into a dummy load.

Power output seems steady and the same as it always was, I just seem to need a lot more CAR control these days.

Possibly Related:
Unable to do the transmit tuning procedure with the drive control at 12:00. I have to crank it to 1:00 to get the meter to move.

Is more CAR control "normal" after adding a CW filter?

or,

Did something fail?
Do I have to realign everything after adding the CW filter?
Anywhere should I focus my tuning efforts?

Tools available at hand:
Frequency counter
Digital volt meter
Kenwood station monitor
oscilloscope

I have a VTVM, but it is a $5 hamfest Heathkit unit and I don't trust the results I see while I use it.
I don't have a tone generator beyond the marker tone and the tones I can inject from the station monitor.

3.3 and 9 volt stuff looks normal.
HV looks to be normal with minimal sag.

Hey thanks in advance for any clues to my high CAR requirements.
Sincerely, Stephen

42179. Re: INTERMITTANT RX SENS

I just picked up a TS-830S and the receiver had the intermittence problem. The peculiar thing was that normal reception returned when I gave my antenna rotator a kick (it's a windscreen wiper motor switched by relays) and then faded again after a minute or so.

I went through the basic cleaning and servicing of contacts on the RF board and found to my surprise that when I tried to remove the vertical connectors for input and output of the RF board, the entire assemblies came away from the PCB leaving neat little holes in the solder joints under the PCB - there were dry joints! Removing the RF board and reflowing connector joints seems to have cured the problem.

As for the rotator switching? I can only assume there was enough of a transient induced in the antenna, and therefore in the RF board input, to temporarily close the circuit where corrosion had formed in the dry joint (not sure what the physics are, but this is occurring at a very small physical scale). These dry joints have been in there for 35 years, so it's anyone's guess as to what was going on chemically in terms of conductivity.

So my advice: reflow the main connectors and components on the main RF signal path if you're getting partial sensitivity loss, and work your way outwards to the receiver control and drive circuitry (AGC, VFO etc.) depending on the severity of sensitivity loss. As well as good cleaning and lubrication of contacts, of course! Then you could be looking at actual component failure after that.

73,

John ZS1ZC.

>
> Bill,
>
> What Terry said is 100%, however, as I am the lucky owner of two 530s, I had a similar problem years ago and it actually related to the RF att switch on the front panel. Try giving it a little wiggle\push in out before cycling through transmit and see if that helps. Mine just had a build up of age in it, I gave it a good blast of deoxit and cycled the switch numerous times, blew out with compressed air and it appeared to fix it, been good for 5+ years.
>
> Remember if you going to go into the PA cage, make sure the radio is disconnected from power and you have discharged the HV, the voltages here are lethal! If it isn't the RF att switch, my money is on the molex connector, either dry joint or just dirty. As Terry said just replacing relays on a hunch is pointless in my opinion and applying heat the the foil track for too long can cause them to lift, so why introduce another problem without looking at the typical easy solve first.

>
>
>
>
> You are all talking about very different relays. K0ZL is talking about the 4PDT flat pack aux relay which does cause several intermittent problems. Ordinarily I would advise you to troubleshoot this condition by studying the RX path from the SO-239 to the RF board and first exhausting the experiential based items followed by signal injection/signal tracing and not just replacing a relay on a guess. I have seen poor solder connection at the So-239 where tinned lead will actually pull out, dirty RF attenuator switch, dirty RF board molex Conn 3, or bad solder connection at Conn 3.
>
> The antenna T/R relays for the TS-530 and the TS-830 are different animals. Both are located under the PA cage in metal shield cans. The TS-830 uses a plug in Omron MX-2P and the the TS-530 uses a miniature solder in Fujitsu FBR321DO12. It is Kenwood part number S51-2407-05 and no longer available. Also, the two antenna T/R relays will not interchange. I have never seen a MX-2P in a TS-530, but have heard of at least one owner who reports one installed which I believe is a mod unless it is an export version of the 530. You need to determine which configuration you have and easy to do by pulling the shield can.
>
> As to the Antenna T/R Relay causing receiver de-sensitivity that would not be common in my experience. The NC contact in this relay sees virtually no current unless the rig has been exposed to ESD. The contacts cannot be cleaned on the TS-530 FBR Ant T/R relay.
>
> If you have the original clear plastic case Omron LZN4 flat pack Aux relay cleaning the contacts can be done, but in my experience will at best be a temporary fix. The LZN4 is no longer available, but can be replaced with a Aromat NF4EB or similar. I suggest buying one from Ken or Jim and replacing.

Stephen: Couple of things come to my mind. 1. Bad CW filter Or 2. Bad Filter switching diode D7 or D8 Or 3. Not turning D7 and D8 full on.

1. If you look at TX Level Diagram you will see input RF voltage at the filter should be approx 25mv rms or 71mv P-P and at the output should be approx 19mv rms or 54mv P-P. Normal to have some filter insertion loss. Can measure this with RF millivolt meter or O-scope at the cathodes of switching diodes D7 and D8. TX Level Diagram levels were taken at 14.175 by loading into dummy load for approx 100watts output and then flip off the SG switch and record the drive levels.

I have covers on my TS-820 at this time so cannot measure the RF voltage at input and output of my CW filter and dont see in my notes that I have recorded it. Perhaps Robert or Joe can tell you what typical goes in and goes out levels are for their 820s? If not, I can remove cover and measure for you along with the Car Level position if you need it.

I am not familiar with the specs for your station monitor in O-scope mode. If it is 20mhz BW scope then your measured P-P levels will be low at 14.175mhz by approx 15%.

2. Measure the dc voltage at IF board Conn IF-2 CW/CWF terminals. Should be 14vdc. This is required to ensure approx 10 ma available to fully turn on D7 and D8.

3. Filter install should not have affected the peak position of the Drive control.

Terry K9TW

Stephen:

I just looked at the SM-220 specs in scope mode noted in the manual on Gordons site and it says scope BW is approx 10 mhz. If that is true it will read P-P voltage of the rf signals very low at 14mhz (less than 30% of the actual value).

After measuring voltages at 14.175 mhz you might want to try loading to 100 watts out on 80 meters and flip SG switch off and then take the CW filter input and output voltage levels. At 3.5 mhz your measured values will be approx 4% low.

It can be confusing if you are taking signal levels and have to remember to make corrections for the Bandwidth of your O-scope.

Terry

Thank you, Terry.

I'm looking forward to checking things out with your suggestions. I think my oscilloscope is rated to 100mhz so that will simplify things instead of trying to use the station monitor as a basic scope. Sorry I didn't mention that sooner.

The peak-to-peak numbers and other hints you have provided will put me on the path to tracking down my low carrier drive. I hope to poke around at the radio some more tonight! I know it is fun when people post up findings and resolutions to problems while the topic is still hot.

P.S.
I gave my fully functional Kenwood TS-50s to my Dad, K2ZZQ. I just have more fun tinkering and learning with this old(er) TS-820. (Even if it seems like it is never quite "fixed.")

John,

The molex plugs are a constant source of many problems, this is why when fault finding it is suggested to pull the molex plugs or give them a slight wiggle. The band switch is also an issue, most of the time it is a build up of dirt\corrosion or a finger on one of the waffer switches has bent out of the way. Best method that has been devised is when finding a dry joint is to remove all old solder sand back the pins and start with fresh solder.

Subject: [TS-520_820_530_830] Re: INTERMITTANT RX SENS

I just picked up a TS-830S and the receiver had the intermittence problem. The peculiar thing was that normal reception returned when I gave my antenna rotator a kick (it's a windscreen wiper motor switched by relays) and then faded again after a minute or so.

I went through the basic cleaning and servicing of contacts on the RF board and found to my surprise that when I tried to remove the vertical connectors for input and output of the RF board, the entire assemblies came away from the PCB leaving neat little holes in the solder joints under the PCB - there were dry joints! Removing the RF board and reflowing connector joints seems to have cured the problem.

As for the rotator switching? I can only assume there was enough of a transient induced in the antenna, and therefore in the RF board input, to temporarily close the circuit where corrosion had formed in the dry joint (not sure what the physics are, but this is occurring at a very small physical scale). These dry joints have been in there for 35 years, so it's anyone's guess as to what was going on chemically in terms of conductivity.

So my advice: reflow the main connectors and components on the main RF signal path if you're getting partial sensitivity loss, and work your way outwards to the receiver control and drive circuitry (AGC, VFO etc.) depending on the severity of sensitivity loss. As well as good cleaning and lubrication of contacts, of course! Then you could be looking at actual component failure after that.

73,

John ZS1ZC.

Stephen:

I once bought a used SSB filter for a TS-820 that supposedly was tested by the previous owner. LSB was fine. On USB it only worked if you used a carrier module USB signal with a frequency that was substantially outside of nominal.

Clearly, filters can have excursions outside the nominal center frequency for no obvious reason. Aside from that, if you look at the INRAD procedure I posted in the Files section you will see that they actually recommend aligning the radio to the filter rather than to a nominal center frequency. You can't change the filter frequency (although I have been tempted to try a hammer) so you have to change the radio to match the filter.

So you might:

1. Make sure the carrier module frequency is correct.
2. Try moving the carrier module frequency around a bit and see how that affects CW output.

Good Luck!

Robert

Chris,

The TS-520 requires a "high impedance" microphone, 50K ohms (see the TS-520 operator's manual). The Heil pro 6 microphone is a "low impedance", 600 ohm, microphone.

Ok-- I got confused because TX level diagram were developed at 14.175 and I had that stuck in my old head, but you will not be measuring the drive levels at that point on the diagram. You will be back at the output of the Balanced Modulator.

So no reason to load on 80 meters due to scope bandwidth limitation affecting accuracy of the measurements. You wont be measuring any rf drive levels at 14.175 mhz. You will be measuring the CWT carrier osc output from the balanced modulator which is under 9 mhz.

If you will be using a scope with a 100 mhz BW you will need no correction to the P-P levels you will read at the input and output of the YG-88C filter. Not so if using the SM-220 if it truly is limited to approx 10 mhz BW.

I agree with you 100% Dave.

If the solder never really wetted to the pin I have never been able to get it to re-flow very well. The pin has oxidized over the years. I always remove all old solder (I use a Hakko 808 but solder wick will work) and then remove the oxidation off the pin either with lite sanding or filing and then apply new solder. Makes a very big difference in quality of the soldering. Yes the Pins are plated, but no concern about removing it where you will be applying solder. Clean bright connection is what you need for a good solder connection. Plating only matters at the male/female socket to pin interface.

I also take good look under magnification to make sure no hair line crack between the trace and the pad. This does happen and can give you fits.

I never remove and install any board without inspecting every molex connector under bright light and magnification. I always re-insert the plug back in to the connector body so that all the pins are fully seated and then I rock connector side to side and watch to make sure I dont see any pin movement or any circumferential crack running around the solder cone. Very easy to see.

I have pulled off my share of connectors and not a fun thing.

I agree with Robert that you should also measure the CAR-2 frequency and level. I would measure it at the IF board at Conn IF-5 pin 13. It should be 8830.7 at approx 300 mv.

If you have good spec frequency and level applied to the board then I would measure filter input and output levels at the switching diodes as I previously suggested. If you find it low at the output of the filter or the insertion loss is greater than what is shown on TX level diagram then go ahead as Robert suggests and vary the Osc frequency by varying trimmer TC-1 on CAR-2 board.

Also make sure you have 14vdc being provided by the mode switch to turn on the filter switching diodes.

Terry (K9TW),

Thanks for the long post!!! I really appreciate your time and effort to explain all this.

I may give it a try this weekend (if I can borrow a better meter than the one I have) and see what I can find out. I'll post back with updates! :-)

Thanks again!

>
> There are several places you can measure the AGC bus voltage. On the IF board at Conn IF-3 Pin 11 for example. You need at least a 10 to 11 meg ohm meter. Even that meter will pull the voltage down some. Should have approx 3 vdc with RF gain full CW. If lower or missing common to start by measuring at it source and cleaning Aux relay contacts that switch it.
>
> A short lesson....The RF and IF amplifiers in the radio are all dual gate mosfets. We call these "gain controlled" stages. We use a variable positive dc voltage (approx 3.5vdc) applied to Gate 2 of these devices to automatically control the gain of these devices. We call this control voltage AGC. This 3.5 vdc control voltage is derived from the RF-1 voltage on the AF-AVR board. With approx 3.5vdc applied to the Gate 2 of these devices they have maximum gain and as the voltage is lowered the gain is lowered (assuming all other required dc voltages to the devices is to spec).
>
> Two things normally lower this control voltage....receiving a strong off air signal and you running RF gain pot back CCW. The S-meter simply monitors the AGC bus line and when it sees the voltage go down it moves the meter up scale. Also, If the AF-AVR board fails you will have no RF-1 to supply the AGC bus so that is why I suggested you also measure it.
>
>
> You have two identical relays in the radio. One is the Aux relay that controls functions like switching the AGC and ALC bus line voltage and the other is your Antenna TR relay. These are plug in relays and very easy to remove and clean. Pull the Aux relay and carefully remove the plastic cover and clean the NC and NO contacts by wetting strip of printer paper with Deoxit and placing between the contacts and applying gentle pressure to the movable armature and pull the paper thru. Should see black traces on the paper. Do this several times and then blow out relay with canned air.
>
> When you report you had good receive one moment and then the level went down or became nearly non-existent and the S-meter is now pegged it sounds like the AGC bus voltage available at the IF Board and RF board to be applied to Gate 2 of the IF and Rf amp devices

is very low.
>
> So I still recommend you check RF-1 on the AVR board and make sure it is available and set per the service manual. First step in alignment is checking and setting the regulated 9vdc and the RF-1 voltages.
>
> Remove the bottom cover of the radio after line cord has been unplugged and rig allowed to sit for awhile to ensure filter caps have bled off. The Aux Relay is about in center of radio next to two vertically oriented filter capacitors about on a line back from the VFO knob. The Ant relay is under a metal shield can in rear corner. You can remove both and clean contacts. Some folks rotate the position of these relays from time to time to place them in different service. Kens Electronics in Kalamazoo Mich has NOS replacements. He has a website. Not a bad idea to have a spare.

You do not need a meter to clean the aux relay. If that doesnt work then a meter will be required to troubleshoot.

> >
> > There are several places you can measure the AGC bus voltage. On the IF board at Conn IF-3 Pin 11 for example. You need at least a 10 to 11 meg ohm meter. Even that meter will pull the voltage down some. Should have approx 3 vdc with RF gain full CW. If lower or missing common to start by measuring at it source and cleaning Aux relay contacts that switch it.
> >
> > A short lesson....The RF and IF amplifiers in the radio are all dual gate mosfets. We call these "gain controlled" stages. We use a variable positive dc voltage (approx 3.5vdc) applied to Gate 2 of these devices to automatically control the gain of these devices. We call this control voltage AGC. This 3.5 vdc control voltage is derived from the RF-1 voltage on the AF-AVR board. With approx 3.5vdc applied to the Gate 2 of these devices they have maximum gain and as the voltage is lowered the gain is lowered (assuming all other required dc voltages to the devices is to spec).
> >
> > Two things normally lower this control voltage....receiving a strong off air signal and you running RF gain pot back CCW. The S-meter simply monitors the AGC bus line and when it sees the voltage go down it moves the meter up scale. Also, If the AF-AVR board fails you will have no RF-1 to supply the AGC bus so that is why I suggested you also measure it.
> >
> >
> > You have two identical relays in the radio. One is the Aux relay that controls functions like switching the AGC and ALC bus line voltage and the other is your Antenna TR

relay. These are plug in relays and very easy to remove and clean. Pull the Aux relay and carefully remove the plastic cover and clean the NC and NO contacts by wetting strip of printer paper with Deoxit and placing between the contacts and applying gentle pressure to the movable armature and pull the paper thru. Should see black traces on the paper. Do this several times and then blow out relay with canned air.
> >
> > When you report you had good receive one moment and then the level went down or became nearly non-existent and the S-meter is now pegged it sounds like the AGC bus voltage available at the IF Board and RF board to be applied to Gate 2 of the IF and Rf amp devices is very low.
> >
> > So I still recommend you check RF-1 on the AVR board and make sure it is available and set per the service manual. First step in alignment is checking and setting the regulated 9vdc and the RF-1 voltages.
> >
> > Remove the bottom cover of the radio after line cord has been unplugged and rig allowed to sit for awhile to ensure filter caps have bled off. The Aux Relay is about in center of radio next to two vertically oriented filter capacitors about on a line back from the VFO knob. The Ant relay is under a metal shield can in rear corner. You can remove both and clean contacts. Some folks rotate the position of these relays from time to time to place them in different service. Kens Electronics in Kalamazoo Mich has NOS replacements. He has a website. Not a bad idea to have a spare.

Do you have the Service Manual? If not must download it.

I assume you are asking about the Carrier Osc? If so, the manual will show you it is developed on the PLL board and adjusted there. It leaves there and is applied to the IF Board at Conn 8 Pin 1.

See Step 3 of the Service Manual for initial level and frequency adjustments.

Aside from that, if you look at the INRAD procedure I posted in the Files section you will see that they actually recommend aligning the radio to the filter rather than to a nominal center frequency. You can't change the filter frequency (although I have been tempted to try a hammer) so you have to change the radio to match the filter.

From: Mike
Topic: 42183 Message: 42195

Chris,

I see this request quite often on this group and other ham forums. You must provide a means to match the differences in the speaker/headphone and microphone impedance between the Pro 6 and the TS-520.

The TS-520 has an "4 to 16 ohm" speaker/headphone impedance range while the Pro 6 headphone speaker has a "200 ohms" impedance.
The TS-520 has a "50,000 ohm" microphone impedance while the Pro 6 has a "600 ohm" microphone impedance.

I do not see any "accessories" indicated in the Pro 6 Product sheet link to "headset adapters" that will allow the Pro 6 to work properly with the TS-520. If you ignore the microphone and headphone/speaker impedance differences between the Pro 6 and the TS-520 I am sure you will NOT be satisfied. My advice for you is to write Heil Sound and ask them if they have impedance matching accessories for the Pro 6 that will allow it to work with the TS-520.

The Heil Sound Pro 6 set "Product sheet" is available at the following link.

http://www.heilsound.com/amateur/products/prosetelite/

Scroll down the page and click on "Product Sheet".

From: kd0fds
Topic: 42178 Message: 42196

OK team. Thanks for all the help so far. I think Terry's #3 idea might be the first road to repair.

On the IF2 connector's CW and CWF pins, I have 12.35 volts.

I also have 12.11 volts on pin 5 on the RF board's RF1 connector.

So...Where does the 14VDC on the CW and CWF pin come from?

Back at the rectifier board, there is a pin labeled "14" with a red wire on it. I show 14.15 VDC here, but I also THINK I saw a perfect sawtooth waveform on this pin too. Hmmm. This might actually be "normal" because red seems to be the wire color for all the panel lights and I think they are AC if I recall. I think purple wire is the 14VDC back at the mode switch and stuff.

Additional reading/info below.

What I learned so far:
TAKE NOTES while you work!
My 14VDC seems low at 12.35VDC.
I gotta fix or replace my VTVM with a rf voltmeter I trust so I can follow the TX levels in the manual.

Diodes D7 and D8 up by the filter seem to be fine showing about .535volts drop forward biased, and seem to block just fine when when I hook the meter up backwards.

I think it is Q7 on the AF AVR board with the big heat sink on it.
Well that heatsink is too hot to leave a finger on it, but it is "touchable." A possible sign that there is a short somewhere drawing excessive current and lowering the voltage?

Speaking of the AF AVR board, what do VR2 and VR3 do anyway?

>
> Stephen: Couple of things come to my mind. 1. Bad CW filter Or 2. Bad Filter switching diode D7 or D8 Or 3. Not turning D7 and D8 full on.
>
> 1. If you look at TX Level Diagram you will see input RF voltage at the filter should be approx 25mv rms or 71mv P-P and at the output should be approx 19mv rms or 54mv P-P. Normal to have some filter insertion loss. Can measure this with RF millivolt meter or O-scope at the cathodes of switching diodes D7 and D8. TX Level Diagram levels were taken at 14.175 by loading into dummy load for approx 100watts output and then flip off the SG switch and record the drive levels.
>
> I have covers on my TS-820 at this time so cannot measure the RF voltage at input and output of my CW filter and dont see in my notes that I have recorded it. Perhaps Robert or Joe can tell you what typical goes in and goes out levels are for their 820s? If not, I can

remove cover and measure for you along with the Car Level position if you need it.

You do not have to go to Heil only, you can hit any audio store and ask for a matching transformer for the Mic. It is a device that goes inline. I have a few of them for my sound system to provide the conversion. As far as the headphones, that can be repaired with the install a simple audio transformer 8 ohms to 200, probably at radio shack. I believe they may have some mic devices as well. Brad KB2CHY

42198. Re: ts-820. CAR control cranked. < 14VDC at CW pin

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-22 17:08:46 UTC
From: Terry Wagoner
Topic: 42178 Message: 42198

1. It is only called the 14vdc bus. It will not supply 14vdc to the boards where you see 14 indicated at a pin. If you measure at the Rectifier board you should have approx 14vdc. It will have a sawtooth ripple as has been no filtering yet. As you move from the transformer secondary and rectifier diodes to the Pi Filter (consist of two electrolytic filter caps and a choke in a C-L-C configuration) you will find approx same voltage at positive terminal of C1 filter input capacitor that you had at the rectifier board. So 13.9vdc is ok here. Then at positive terminal of C2 filter output capacitor you should see voltage reduction perhaps around 12.80 or so. This is due the affect of the choke. This 12.80vdc is then routed to all the places where "14vdc" is indicated on boards. There at these molex connectors you will find slightly lower voltage say around 12.75vdc.

Your 12.35vdc at CW/CWF is a little low, but not enough to cause filter switching diodes to not turn on sufficiently. It may be that C1 and C2 are getting a little tired?

2. RF-1 is Pin 4 and not Pin 5 at the RF board.

3. Follow the schematic CW/CWF is fed from the mode switch.

4. You cannot use a standard RF probe and VTVM to measure the low levels at the input and output of the Xtal filters. A germanium diode probe has a barrier voltage of approx 250mv. If you try to measure 25mv with it your VTVM may only just slightly deflect or not at all and if it does will not read accurately. Read the RF probe primer I posted here very recently. For very low signal levels you have two choices. RF millivolt meter or an O-scope.

5. Q7 is on a small heat sink and should not be so hot cant hold finger on it. Series pass regulators are inefficient and they do waste power thus need for a heat sink. It will run warm, but not barely touchable. This means there may be a problem on the 9VDC bus? What is the regulated 9vdc voltage?

6. VR-3 is Side Tone volume

7. VR-2 is used to set the RIT so it does not change VFO frequency when you turn it on with RIT at 1200. The service manual describes how to use the Marker to adjust VR-2.

8. Do you have an RF signal generator with a calibrated step attenuator? If so, can leave CAR LEVEL Pot turned all the way down CCW and inject 8.830 mhz at D7 and use sig gen in lieu of carrier from balanced modulator to drive the rig. Set the output for approx 25 mv or -19dBM. You can also swing the frequency to see if the filter center frequency is not per spec.

42199. RF Probe for IM-18 VTVM

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-22 18:17:31 UTC
From: paul.nussbaum
Topic: 42199 Message: 42199

Replaced the driver in my 820S, still no ALC in TUN mode, want to run the TX level measurements. Anyone have a spare RF probe?
Thx,
Paul
AD5FT

42200. Re: ts-820. CAR control cranked. Wow thanks Terry.

OK, Thanks, Terry. I have had a chance to read all the replies and do some more searching on this amazing forum. I think you have provided enough clues for me to fix my TS-820 now.

One thing I should probably try would be to remove the CW filter and re-test. After all, it is the most recent change and therefor a good place to start looking.

Thanks for the description on VR2 and VR3 on the AF-AVR board. I recall adjusting them in the past, but again, I need to take NOTES!

I have found a lot of great posts related to the "14"VDC path from both you and Mike. All the clues are there. Step one might be a rig safety electrolytic capacitor replacement project. (C1 and C2 included) You guys have me sacred about the 2 axial capacitors on the rectifier board!

9V is currently at 9V. (no changes were required when measured last night. Same with the 3.3 Volt adjustment.)

overheated Q7 is still a "concern."

I'll try to make some progress tonight with my service manual and the tools/parts I do have. Unfortunantely, I don't have an RF signal injector yet. It is a pretty big limiter in keeping my TS-820 alive. I'll have to "address" that.

thanks again,
Stephen

>
> 1. It is only called the 14vdc bus. It will not supply 14vdc to the boards where you see 14 indicated at a pin. If you measure at the Rectifier board you should have approx 14vdc. It will have a sawtooth ripple as has been no filtering yet. As you move from the transformer secondary and rectifier diodes to the Pi Filter (consist of two electrolytic filter caps and a choke in a C-L-C configuration) you will find approx same voltage at positive terminal of C1 filter input capacitor that you had at the rectifier board. So 13.9vdc is ok here. Then at positive terminal of C2 filter output capacitor you should see voltage reduction perhaps around 12.80 or so. This is due the affect of the choke. This 12.80vdc is then routed to all the places where "14vdc" is indicated on boards. There at these molex connectors you will find slightly lower voltage say around 12.75vdc.
>
> Your 12.35vdc at CW/CWF is a little low, but not enough to cause filter switching diodes to not turn on sufficiently. It may be that C1 and C2 are getting a little tired?
>
>
> 2. RF-1 is Pin 4 and not Pin 5 at the RF board.
>
> 3. Follow the schematic CW/CWF is fed from the mode switch.
>

> 4. You cannot use a standard RF probe and VTVM to measure the low levels at the input and output of the Xtal filters. A germanium diode probe has a barrier voltage of approx 250mv. If you try to measure 25mv with it your VTVM may only just slightly deflect or not at all and if it does will not read accurately. Read the RF probe primer I posted here very recently. For very low signal levels you have two choices. RF millivolt meter or an O-scope.
>
> 5. Q7 is on a small heat sink and should not be so hot cant hold finger on it. Series pass regulators are inefficient and they do waste power thus need for a heat sink. It will run warm, but not barely touchable. This means there may be a problem on the 9VDC bus? What is the regulated 9vdc voltage?
>
> 6. VR-3 is Side Tone volume
>
> 7. VR-2 is used to set the RIT so it does not change VFO frequency when you turn it on with RIT at 1200. The service manual describes how to use the Marker to adjust VR-2.
>
> 8. Do you have an RF signal generator with a calibrated step attenuator? If so, can leave CAR LEVEL Pot turned all the way down CCW and inject 8.830 mhz at D7 and use sig gen in lieu of carrier from balanced modulator to drive the rig. Set the output for approx 25 mv or -19dBM. You can also swing the frequency to see if the filter center frequency is not per spec.

Hi Paul, when I needed a RF probe I went on line and made a simple one from plans that I found. Used and RCA connector on top of my dummy load, output side and worked fine or used elsewhere where measurement was needed. I also have 2ea. VTVM heathkit 18s.

BEST 73 and GODS BLESSINGS, MIKE & Princess Ruth.

This is the final time I will respond to this. I have tried very hard to describe what you need to perform TX Level Diagram testing. When you post a request like this it makes me think you did not read anything that I provided and clearly some others who are responding have no idea how to troubleshoot transmit drive level problems.

1. What kind of probe do you want? I have told you multiple times you need TWO different germanium diode probes. I even suggested where you might get a Heath PK-3.

2. Probe 1: A SINGLE GERMANIUM DIODE PROBE for measuring the output of the Transmit Mixer on the RF board. Approx 2 rms volts. That probe cannot be used to measure any other RF drive voltages. TIF is too low and beyond Transmit mixer output the levels are too high. It can be used for measuring Het Osc and VCO signals which may be required if you need to troubleshoot the Transmit Mixer.

3.Probe 2: A THREE GERMANIUM DIODE PROBE for measuring the RF drive at the Plate of the 12BY7A tube and at the control grids of the 6146 Final tubes. Approx 65 rms volts and 47 rms volts respectively. If you try to measure these points with a typical single diode probe you will very likely burn out the diode.

4. To measure TIF signal you will need a O-scope or a RF Millivolt meter. Measure TIF last. Start at the Control grid of the 6146 finals and measure DC operating bias and RF drive levels.

5. As I previously posted, the only way you can use a SINGLE GERMANIUM DIODE probe to measure the rf drive at the 12BY7A plate and the 6146 control grids would be to reduce the TIF signal level by keeping CAR LEVEL Pot reduced (CCW) so that you do not exceed the PIV of the probe diode and burn out the diode. Even with experience it would be difficult and easy to mess up.

So I just dont understand how you can ask if any one has an RF probe. Just not specific enough for an intelligent response.

Good Luck--Terry K9TW

Stephen:

Yes you could remove it and see if rig tunes as it did before and does not require significantly more CAR level. This would tell you that Carrier Oscillator level is close to spec. However, tells you nothing about the CW filter or its switching diodes.

All of us had to start building test bench slowly over time. I and Mike and others have posted many times on what is needed at a minimum to troubleshoot and maintain a Kenwood Hybrid and in what order to buy each piece. You dont need a lab grade RF bench, but something on order of Heathkit level is needed at a minimum. Sometimes there are alternate methods to accomplish the steps and other times you have to bite the bullet and realize the easiest and best method is to use the service manual prescribed test gear. There is no "only one way" but very often one way is clearly superior to others.

Filters can be swept manually and the response shapes plotted on graph paper. I bit tedious but was done that way for years. I have notebook full of graphs before I got a decent sweep generator. Now I am lusting for VNA and/or Spectrum Analyzer and Tracking Generator. Even the old manual method requires a rf signal generator and a means to detect the RF output voltage at the frequency steps you inject.

I dont know any way to measure the filter insertion loss without a means to measure the RF voltage at the input and at the output of the filter. Can use the rigs internal Carrier Osc signal, but still need a RF millivolt meter or an O-scope. No way around it.

If you want to test the filter on the bench you can do that but you should terminate the input and output. I wont go into that test procedure here. Once you get correct gear I highly recommend you sweep any used filter on the bench before installing in rig.

Absent a RF signal generator I think it is best for you to leave filter in the rig and use the Car Oscillator as your signal source. If you have a near by club might ask if someone will loan you an O-scope or RF millivolt meter or let you bring rig to their bench.

I freely do that for folks who are really trying to help themselves.

Take Care
Terry K9TW

Clean and working as it should BUT missing the cord from the stand to the radio.
Substituted the cord from another MC-50 and all is A-OK!. $35 as-is + USPS.

If you want something to do while waiting on construction or purchase of your RF PROBES you can take the DC voltages at the socket of your new Driver Tube. Ordinarily would not do this unless TX Level Diagram results indicated a problem at the Driver Tube. However always good to take the voltages and record in your notes. You can take these with tube pulled, but better to take with load on the tube.

You have to be careful taking these on the foil side of the board accessing the tube socket pins thru the drive chain. I use a micro needle point probe tip insulated with heat shrink or a piece of insulating jacket stripped from small gauge hook up wire.

Take these with heaters on and SG switch Off and flip to Send (I always have dummy load connected for safety in case of inadvertent transmit). Pay close attention to the control grid operating bias voltage and the screen grid voltage.

If you already took and reported these voltages I am sorry as I do not recall the results.

Here are measured values from my notes.

Pin 1 Cathode-- R = 0.32vdc T = 5.25vdc

Pin 2 Control grid-- R = -42.3vdc T = 0.36vdc

Pin 7 Plate-- R = 333vdc T = 305vdc

Pin 8 Screen grid-- R = 248vdc T = 219vdc

Note: With 5.25vdc on cathode you will have approx 35ma cathode current which is full load for a 12BY7A Class A RF amplifier.

Terry K9TW

Terry,
Apologies for making you think I was not paying attention. I'm still trying to collect the things I need. There are things I won't really understand until I'm hands-on into it, and all I've been able to do so far is learn, plan, and purchase.

I didn't forget your notes about the probes; I even copied them into another document that has many of your other notes because the navigation mechanics of this forum is quite frankly the worst I've ever used... takes me forever to locate anything amongst the 45% duplication of posts, 45% white space, and 10% unique content.

I have the IM-18 and the AC/DC probe. I've calibrated it but have not used it yet.
I received replacement drivers today and put one in... no difference.
I pulled the relay and gave it the cleaning treatment.

While waiting on getting the proper RF probes, I am looking for things to measure / test.

My earlier measures, which seem good:

Pin 5 of the 6146 grid #1:
Finals circuit diagram specs (-100V/-55V)
I measure both tubes at
-99.5V before transmit
-57.5V during transmit
.
ACL ref voltage spec (3.3V), I measure 3.28V

12BY7A Pin 2 grid #1
RF board circuit diagram specs (-43V/0V)
I measure
-40.2V before transmit
.003V during transmit

12BY7A Pin 8 Grid #2 (screen)
RF board circuit diagram specs (250V/210V)
I measure
255V before transmit
224V during transmit

I will try to measure the driver tube pin 1 and 8.

I'm also looking at measuring Q5 on the RF board as that is indicated in the service troubleshooting guide for ALC.

I sent an email to the man you suggested might have some spare probes after he upgraded his instruments... never got a reply.

Now I'm just thinking out loud...
The service troubleshooting guide also mentions coil mis-alignment as a possible cause...

this problem did occur during coil alignment. I don't suppose there is some way to see if that in itself could be the trouble? The problem is on all bands, but I know some of the band coils are interactive.
Any danger in repeating the coil alignment and rotating the slugs far both ways to hunt for ACL indication? Assuming adequate rest time for the driver...

Thanks,
Paul

42207. VTVM/RF Probe Reality Check-

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-23 03:30:31 UTC

Topic: 42207 Message: 42207

All this chatter about RF probes and VTVMs made me pull my Heathkit out of the cabinet. I've been using my scope for most measurements so I wanted to see how closely the scope and the VTVM tracked one another with respect to RF levels. Hoping someone can set me straight on what I am seeing-

I have a Heathkit IM-11, Heathkit PK-3 RF Probe, Fluke Model 77, a Wavetek sig gen and my trusty Tektronix 380 Oscope.

I connected the my sig gen to the scope and set the sig gen for a 1 Mhz, 2V pk-pk signal. If I do the math, a 2 V pk-pk signal is .707 Vrms.

I now take the Heathkit IM-11 (which I just calibrated), PK-3 RF Probe and connect it in parallel with the scope. The scopes readings do not change, however the VTVM only measure about -0.550 VDC. I then disconnect the RF probe from the IM-11 and clip lead it into the Fluke 77. It measures about the same as the IM-11 -0.565 VDC.

So the question is why does the calculated value not match the meter readings? A 2V pk-pk signal should give a -0.707VDC reading on the meters, correct? Am I missing some scaling factor Or a diode drop somewhere due to the RF probe construction?

Thanks, Jim, KC1RM

Learning and training is not "chatter".

You are looking at classic Electronics 101 2x scaling error.

Your Wavetek attenuator is only accurate when rf output is connected to a reasonably short 50 ohm cable terminated by 50 ohms.

I have my scope set up with Channel 1 for 1 meg ohm 10x probe input and Channel 2 terminated with a Tektronix 50 ohm 5 watt feed thru. A feed thru or terminator is available from ebay. Absent one can use a bnc tee and terminate the open tee with 50 ohm resistor.

You dont have 2v P-P output. You have 1.57v P-P output. 1.57/2 = 0.785 x .707 = 0.555v rms.

Look for Boonton Notebook 23 on web. It has a Thevenin Theorem explanation of what you are seeing.

Also, here is explanation:
http://www.effectivebits.net/2011/12/whats-wrong-with-my-function-generator.html

This affect has fooled all of us at one time or another and best way to avoid it is to have scope that has 50 ohm input or leave one channel set up as I do.

Paul: Remind us again what are the current symptoms? For example: No ALC on all bands and no RF output on all bands? OR-- No RF output just in Tune mode OR--No ALC, but good rf output on 10 meters only?

OK sorry I launched. Getting tired of being blown off, ignored and/or undermined on the forum and by those who sneak around off list. I had guy tell me another guy wrote him off list and said all you need is a 2 diode probe and didnt matter what kind of diode. Well that is crap. We are talking RF voltage measurement and not rf voltage detection. Yes could use a 2 germanium diode probe at grids of finals, but will likely blow it up on plate of driver tube. What I am telling you limits the individual diode to measuring 30 rf volts. This gives you head room. Why risk wrecking your probes?

Yes forum is not easy to search on prior post. I do use the advanced search keyword and it does bring back a lot to sort thru. I should have asked Gordon if the RF probe diode primer merited being placed in the Files section. Would be nice to go thru files and weed out a lot of the low value stuff.

You have done some nice work. Remember the -57.5 on 6146 control grids. Now all you need to do is measure the RF drive level. You will need greater than 57.5/1.414 = 40.7 rms rf volts for any ALC indication.

Your Driver tube operating bias and sg voltage looks good. Be surprised if you do not have approx 5 vdc on the cathode. Appears driver tube is turned on and functioning fine. Cant tell for sure until you can measure rf in and rf out.

Your ALC reference voltage is OK. Now you can also measure it actually on the ALC bus where it is used, but best to do that with VTVM as easy to pull it down with most meters. Can try with your DMM. Go to RF board Conn RF-3 Pin 6 and measure with SG off and flip to send. Q5 can fail but start by measuring dc ALC voltage at Pin 6.

Sorry Jimmy did not respond. He did upgrade to Boontons and I know he had a couple of PK-3 probes and I think one was a new kit. He and his wife have had heart related health issues recently. I will try to contact him.

It is very unlikely that your adjustment of a Drive or Mixer coil during coil pack alignment is reason for no ALC indication and no RF output on all bands. Yes there is some degree of interaction but not to that degree. I suspect it is coincidental. Typically bad molex connector or dirty relay contact affects all bands. I would not go back to coil pack until you get ALC indication back.

Are you talking about using a the RF detector circuit on a Heath Cantenna for an rf probe to run TX Level Diagram or troubleshoot low level RF circuits?

If so, I am sorry but there is no way you are using it on any boat anchor to measure low level rf drive voltages.

It is an RF detector circuit that measures the RF voltage across the 50 ohm dummy load. It is designed as a tuning/loading aid by providing a relative dc voltage that can be displayed on your multi-meter. It is a terrible test rf probe. We are talking about measuring the rf voltage levels at the input and output of IF crystal filters and TIF signal levels. These are in the 15 to 25 millivolt level range. The Cantenna detector wont even see them let alone accurately measure them.

The RF detector in a Cantenna is designed to detect and rectify high level voltage across the 50ohm dummy load (71 volts at 100 watts and 224 volts at 1000 watts). It is not designed to measure anything. First of all it has a 100:1 voltage divider at its input. It also uses a series diode which means it is fooled by the offset. Also as I previously reported it is very frequency sensitive.

If you placed a bnc on the SO-239 and connected a test lead to it and then connected it to the rf drive path in your Kenwood in an attempt to measure the drive levels you would have realized it wont register any dc voltage at its RCA jack at the levels we are dealing with until you get to the Plate of the Driver tube. There if you had nominal 65 rf volts you would see something on the order of approx 65/100 = 0.65 vdc - 0.25 diode barrier = 0.45 rf volts (not corrected for frequency). At most you could see 0.45 x 1.414 = 0.636 (peak of filter cap). What would reading approx 0.45vdc to 0.636vdc at the plate of the Drive tube tell the inexperienced owner about the state of his rig?

Assuming you are talking about a Cantenna or similar detector it is a very poor recommendation to make to a new person.

I would be interested to hear more about how it worked "fine"?

Oh I forgot to mention I would not connect my Cantenna rf detector to the Plate of the Driver tube or any place where high DC voltage is present as the circuit has no DC blocking/coupling capacitor. If you do that the plate voltage could destroy your diode.

Anyone interested in a Heathkit comeback, there is a survey everyone can take.

I took it yesterday and was fairly long, but if
it helps them with their comeback it will be well worth it.

I did talk with Heil today and they have a part called the xt-1 high to low impedence matching transformer that can be wired into the main cord, I'm looked at the price on it and it is only so I am going to go ahead and figure on getting it along with the proset 6. Chris N5HSU.

> If the solder never really wetted to the pin I have never been able to get it to re-flow very well. The pin has oxidized over the years. I always remove all old solder (I use a Hakko 808 but solder wick will work) and then remove the oxidation off the pin either with lite sanding or filing and then apply new solder. Makes a very big difference in quality of the soldering. Yes the Pins are plated, but no concern about removing it where you will be applying solder. Clean bright connection is what you need for a good solder connection. Plating only matters at the male/female socket to pin interface.
>
> I also take good look under magnification to make sure no hair line crack between the trace and the pad. This does happen and can give you fits.
>
> I never remove and install any board without inspecting every molex connector under bright light and magnification. I always re-insert the plug back in to the connector body so that all the pins are fully seated and then I rock connector side to side and watch to make sure I dont see any pin movement or any circumferential crack running around the solder cone. Very easy to see.

> >
> > I went through the basic cleaning and servicing of contacts on the RF board and found to my surprise that when I tried to remove the vertical connectors for input and output of the RF board, the entire assemblies came away from the PCB leaving neat little holes in the solder joints under the PCB - there were dry joints! Removing the RF board and reflowing connector joints seems to have cured the problem.
> >
> > As for the rotator switching? I can only assume there was enough of a transient induced in the antenna, and therefore in the RF board input, to temporarily close the circuit where corrosion had formed in the dry joint (not sure what the physics are, but this is occurring at a very small physical scale). These dry joints have been in there for 35 years, so it's anyone's guess as to what was going on chemically in terms of conductivity.
> >
> > So my advice: reflow the main connectors and components on the main RF signal path if you're getting partial sensitivity loss, and work your way outwards to the receiver control and drive circuitry (AGC, VFO etc.) depending on the severity of sensitivity loss. As well as good cleaning and lubrication of contacts, of course! Then you could be looking at actual component failure after that.

I didn't realize the word 'chatter' had such negative connotations until
I looked at the definition- I guess I should of used the word
'discussion', which is what I meant.

My question was not with respect to the attenuator setting, it was more
to do with voltage at the end of the wire. Whether it is terminated in
a 50 ohm load or not, if I adjust the vernier on the sig gen to deliver
a 2V pk-pk sine wave as displayed on the scope, shouldn't the VTVM/RF
Probe combination indicate a -0.707 VDC (or there about)?

You are doing the right thing Chris, stick with Heil accessories.

I'm pretty excited about going for the heil proset. I called heil directly and the gentleman I spoke with was real quick to tell me what I needed when I explained what I was looking for. I was able to order the headset and the xt-1 both from giga parts. The xt-1 was only $14.

Topic: 42207 Message: 42219

Jim:

Use your PK-3 to set the open circuit voltage of your Wavetek on 2 mhz. Use low freq to take any bandwidth limitations of the scope out of the equation. With the attenuator set at +13dBm you should read close to 1.0 rms volts with your RF probe/Fluke combo. It will be low by the 25mv to 30mv barrier voltage of the germanium diodes so if you have one diode will read approx 980mv and if 3 diodes then will read approx 900mv. It may also be off if your scaling resistor is 4.7meg which is used for 11 meg meter and your Fluke may be 10 meg. But it should be close to 1.0 rms volts.

Now with your RF probe/voltmeter having verified that your Wavetek open circuit voltage is close to 1.0 rms volts go ahead and measure the Wavetek open circuit voltage (without touching the attenuator) with your O-scope using a 10x 1 meg probe.

My new Rigol DS1102E reads approx 6.0 volts P-P and the Rigol also measures voltages and displays them on the screen and it displays 2.0 rms volts. Note that this is exactly twice the 1.0 rms volts measured by the RF probe. Different scopes will read different P-P levels. To avoid this I always use a Tek 50 ohm feed thru on my Channel 2 vertical input and have it set for 1x. The P-P and RMS voltages then will read correctly

Now terminate your Wavetek test lead with 50 ohm resistor. My Rigol now reads 2.84 P-P volts and the Rigol displays 1.0 rms volts. Right where it should be. By the way same with my 475A with exception of no digital display of measured voltages. I have to convert the 2.84 P-P it is displaying.

To understand this you can draw sig gen equivalent circuit on paper. Use Gen symbol with 2E in the circle and add a 50 ohm resistor in series with the output and bring out a plus lead at top and minus lead at bottom. Then connect different impedances across the plus and minus terminals representing your scope 1 meg ohm probe and 50 ohm terminator. You will be paralleling these two loads across the generator. The generator impedance will be in series with what ever load resistance you place across it. With 1 meg across generator there will be majority of the output voltage dropped across it. With 50 ohms across it the 2E output voltage will divide exactly in half. Half across the internal resistance of the signal generator and half across the load. The Generator voltage will be 2E and the voltage across the 50 ohm terminator will be E.

It is not easy to understand and I am not good at explaining. For now understand it occurs and do as I do and keep one channel of your scope reserved for 50 ohm feedthru for accurate RF signal generator measurements.

As I mentioned the Boonton Note 23 on the web gives a good explanation of this using Thevenin Theorem. Look at Fig d and study it.

42220. Re: ts-820. CAR control cranked = probably the filter itself.

Terry.

I have read some of the hybrid required test equipment posts. I will search and read up on it more today.

Today I use what I have and wish I had more. (I have used my guitar tuner as an AF signal generator for example.)

I worked on the TS-820 last night with my oscillospoce and my frequency counter, the Kenwood service manual, a DMM, and my new TS-820s notebook.

I slipped up on this project from the start. I didn't ask the universal repair question:

"OK. Who worked on this bucket last and what did they do?"
Last action: I added the CW filter.

After checking/adjusting a bunch of stuff, I still had to tune up with the CAR control cranked last night.

I moved the IF1 connector on the RF board to to position "A." Ta-da. No more CW filter in use and no more full clockwise CAR control requirement to get full output. Rig is back to "normal."

I got out the schematic and walked along the CW path so I knew what to try to test. There isn't much on that circuit to look. My current guess? The used filter itself is at fault. I'll re-read Mike's testing the filter stuff in this tread. (Loved the "adjust with hammer" comment.) and the INRAD alignment instructions in the "files" section to learn more.

THE PLAN:

Read up on the INRAD stuff in the files section.
Research bench gear for properly maintaining my hybrid.
I'll order up parts so I can work on the radio in June.

More news in June.
Thanks again, Stephen

>
> Stephen:
>
> Yes you could remove it and see if rig tunes as it did before and does not require significantly more CAR level. This would tell you that Carrier Oscillator level is close to spec. However, tells you nothing about the CW filter or its switching diodes.
>
> All of us had to start building test bench slowly over time. I and Mike and others have posted many times on what is needed at a minimum to troubleshoot and maintain a Kenwood Hybrid and in what order to buy each piece. You dont need a lab grade RF bench, but

something on order of Heathkit level is needed at a minimum. Sometimes there are alternate methods to accomplish the steps and other times you have to bite the bullet and realize the easiest and best method is to use the service manual prescribed test gear. There is no "only one way" but very often one way is clearly superior to others.
>
> Filters can be swept manually and the response shapes plotted on graph paper. I bit tedious but was done that way for years. I have notebook full of graphs before I got a decent sweep generator. Now I am lusting for VNA and/or Spectrum Analyzer and Tracking Generator. Even the old manual method requires a rf signal generator and a means to detect the RF output voltage at the frequency steps you inject.
>
> I dont know any way to measure the filter insertion loss without a means to measure the RF voltage at the input and at the output of the filter. Can use the rigs internal Carrier Osc signal, but still need a RF millivolt meter or an O-scope. No way around it.
>
> If you want to test the filter on the bench you can do that but you should terminate the input and output. I wont go into that test procedure here. Once you get correct gear I highly recommend you sweep any used filter on the bench before installing in rig.
>
> Absent a RF signal generator I think it is best for you to leave filter in the rig and use the Car Oscillator as your signal source. If you have a near by club might ask if someone will loan you an O-scope or RF millivolt meter or let you bring rig to their bench.
